MEDICINE AT THE CROSSROADS

HARVEY CUSHING, M.D.

BOSTON

In April of 1918, a Canadian casualty clearing station had been newly set up, in the emergency of that critical time, at a hamlet called Pernes somewhere near Bethune in Flanders. The surgical "teams," as they were called, hurriedly assembled from where they could be spared, were working on day and night shifts like factory hands to keep abreast of the raw material fed in to them. We dealt with wounds—not the man. For him we had no time. Some far away government took that responsibility and is still paying for it. In the midst of this, on an afternoon while in the course of one more gruesome task, I was suddenly told by a much annoyed Commanding Officer that orders had been received from the A E F for me to report forthwith at a place called Langres.

Anything may happen in time of war, and one asks not why. Langres, as it turned out, was a perfectly safe hill-town half way across France between the headwaters of the Marne and the Meuse. And not knowing whether I was to be demoted for some breach of discipline or made commander-in-chief, with ill-concealed agitation I presented myself there in due course before the C O of what proved to be a training school for Army medical officers. I was informed I had arrived just in time to give the noon lecture on battle injuries of the head.

Of that ill prepared and futile lecture—after which I was dismissed—the less said the better. I was picked up by a sympathetic friend permanently attached in Langres—a first lieutenant, considerably my senior in years, who in normal times was a professional colleague. He offered to take me to lunch at his mess before my departure. On the way there—and I at last approach the point of this recital—we passed, in a narrow street, the open window of a shop in which, concentrated on his work, there sat before a bench an oldish man in shirt sleeves and a leather apron making jack-knives. He wasn't making parts of knives but the whole knife—steel blades, bone handle, and all, and some of them, finished, were hanging in the window alongside a much faded blue tunic with a wound stripe on the sleeve, which told its own story.

Were his knives for sale? Yes, since times were hard, only six francs for the better ones, and we could step in and have a look if we desired. A pocket knife may sometimes be useful to cut red tape, and when I had made a selection he examined the knife carefully, put it back and took another which he said was a better

one. If I didn't lose it, it would last all my days, and would I notice the spring—no breaking of fingernails with a carefully made and tested knife like this—a masterpiece if he said so as shouldn't. So admiring was he of his handiwork I began to think he would not bring himself to part with it, but his decision to do so was suddenly stiffened by the entry from a back dwelling-room of his wife and two children—future jack-knife makers in all probability.

Not long after this, I somehow or other happened to sit in at an informal discussion between two French officers and two American efficiency experts, members of an advisory commission that had been sent to France. Plainly the reason the Allies had not already won the war was their want of industrial organization, their inability, for lack of proper machinery and modern methods, to turn their raw materials rapidly enough into the finished product and to give it wide distribution. The only way to do this effectively was the way we made motor cars in America, each workman contributing his small part, at high speed, in short hours, for good wages.

After much more in similar vein, the senior French officer finally said "This may all be true, gentlemen, but it would be almost better for us to lose the war. The French artisan works because he likes to, often at his home, can turn his hand to many things, is frugal and content with small earnings, can usually make, pretty much with his own tools and hands, some finished product which he can sell. So even in trying times like these, he gets independently to work as his own employer, somehow supports himself, and merely asks to be left alone. Were he forced into being a piece-work specialist he would lose his resourcefulness and independence of action. Should this happen on a large scale, discontent would surely follow and our social order fall to the ground."

That night I fell asleep thinking of the Langres knife-maker. Every foot-soldier should have a jack-knife—not just an occasional officer. There must be a more even distribution of bigger and better and sharper knives. All independent knife-makers in the emergency are congregated in a factory where some do the blades, some the handles, some the assembling of parts, the labeling and packing, the advertising, the selling, the foreign distribution—everyone a specialist in his own line. It becomes a great business, a marvel of efficiency. Jack-knives are quoted on the stock market and prices soar. New machinery is installed whereby synthetic knives can be turned out by the million almost without aid of human hand—and everyone knows the awakening. A glut on the market, a closed factory, all knife-makers out of work, and even those few who still remember how to fashion a good, complete jack-knife from the raw materials no longer able to sell them, join

the others, march on Paris behind the red flag of protest, and demand from the government either a dole or a new sorting of the cards. Whereupon a group of well intentioned philanthropists, sociologists, economists and lawyers, together with two former knife-makers, one now a specialist in corkscrews, the other in synthetic-bone handles, are appointed to study in all its aspects the relation of knife-making to the common weal.

This, after all, is not much of a story—partly a dream at that—and perhaps only by a stretch has it anything to do with present crux in which the medical profession finds itself, overmanned, overspecialized (behold this Congress!), like other necessities of life poorly distributed, an expensive luxury for those of modest means and the subject of investigation by a commission which threatens us with socialization unless we promptly do something to alter our spots, to cast off our long-conditioned reflexes, and put ourselves on a modern chain-store business basis. This for the next twenty-five years at least, and that's as far ahead as there is need to plan, will serve to make everyone—including the doctor—happy, healthy and wise.

A lawyer on the commission goes so far as to use the ugly word "coercion" and when a friend, familiar with jurisprudence, was asked just what that meant, he said "government by force." And to the question whether it would be possible similarly to "coerce" the legal profession into caring for persons of modest means on the same parity as the well-to-do, he replied "No, the lawyers are too smart and there is too large a percentage of them in our legislative bodies ever to bring such a thing about."

A recent leader of public opinion openly states that most of those at present dealing with the sick—meaning more specifically the doctor—have their faces turned toward the past. If history but repeats itself, where else but from the past *can* we learn anything? We certainly can draw little comfort and few admirable lessons from the late present. Nor would this seem to be the time to fly to evils we know not of, but rather to stick firmly to what has proved in the long run the great stabilizer—every honest man with faith, hope and a stout heart going about his own business, with swift punishment for dishonesty and crime. And lest we forget, let us for a moment in reality *turn* our faces to the past.

"The prevalence of crime he assigned to want of employment among the poor, to the idleness and the luxury of the well-to-do, to the recklessness with which the rulers engaged in war, and to the readiness with which merchants were converting arable land into pasture, villages were laid waste and the opportunity of labor was greatly diminished in order to fill the coffers of capitalists. Discharged soldiers, troops of dismissed retainers from the households of the gentry, who, after a life of idleness, were thrown on their own resources, ploughmen and peasants, whose services were no longer required by the sheep-farmers, perilously swelled the ranks of the unemployed and made thieving the only means of livelihood for thousands of the population. A more even distribution of wealth was essential to the country's salvation. To this end were necessary the enjoyment of the blessings of peace, restrictions on the cupidity of the capitalist, improved education of the humbler classes, and the encouragement of new industries."

While this might have been written of many times and places since then, it in effect was what the old sailor Raphael Hythloday had to say concerning the status of England in the sixteenth century. Things were quite different, he said, on the island of Utopia, whence he

had recently returned. There everyone lived in complete social happiness and brotherly love, disdaining money, they wanted for nothing, not even hospital care, and could worship as they chose.

Needless to say, when the crisis came in his own affairs, the author of this more often quoted than read allegory, with the inconsistency that affects mankind, failed to live up to his expressed ideals, attempted to coerce others to his own theological beliefs, and lost his head in the process. Social reformers, no less well intentioned and lovable characters than was Sir Thomas More, sometimes lose their heads though not always in just that way. More's great friend Erasmus wrote a famous skit in praise of folly, and More doubtless knew well enough that "the greatest folly of which a man is capable is to sit down with slate and pencil to plan out a new social world," though we waited almost four hundred years for a student of society to say just that.

Heaven knows there are plenty of things the commoner, including most doctors, would like to see corrected and the sooner the better—dishonesty among those entrusted with other people's savings, less interest in legal procedure and more justice among the lawyers, as examples—and the doctor wonders why, just at this time, when in spite of widespread distress and anxiety the health of the people as a whole is better than ever, he should be particularly singled out and told if he doesn't distribute himself more evenly, stop specializing and charge less, he'll be coerced into doing so. He thinks this highly peculiar, for hasn't he always striven with ever increasing success to eliminate one after another the diseases whose particular care provides his bread and butter? And has he not shared with the priest, from the beginning of the record, in giving a large part of his time to the indigent poor in whom business, finance and the law may be theoretically interested without showing it in so direct and practical a way?

Lay reformers speak lightly of his code of ethics as something long since outworn, but so far it has prevented him, for one thing, from capitalizing for his own benefit his inventions and therapeutic discoveries. If Jenner and Lister had been trained in the point of view of modern business efficiency, instead of being just a plain, improvident country doctor and a young hospital surgeon, whose only desire was to help others, and to stand well in the esteem of their professional fellows, what then? For the discovery of the practical application of ether anesthesia, Medicine has no corresponding hero because someone, having unethically taken out a patent, proposed to sell it to the government for a large sum and very nearly succeeded in doing so—all of which is thoroughly ventilated in five hundred and eighty-two printed pages of testimony before a select committee of the United States Senate to their great waste of time. For what could be their understanding of an ancient profession's precepts in regard to what its votaries may and may not properly do?

It is preposterous, writes the efficiency expert, to say that a man, even a doctor, is not entitled to what he can make out of his inventions. The medical man of the future will pay more attention to prevention than to cure, says the young DPH to his hostess as he accepts his second cocktail. The social reformer, stopping at the corner store for his favorite brand of cigarets, purchases a sixty-cent bottle of the latest "peccatorial" which the clerk says will be good for his (easily preventable) chronic cough, and, dear me, he's almost

forgotten his promise to fetch home Aunt Maria's weekly bottle of Lydia E's Restorer at \$1 25, for though it isn't so restoring as when it contained forty per cent, she still takes it after meals

Knowing their frailties, the doctor doesn't think overmuch of his fellowkind while doing what he can to prevent, alleviate or cure their ills. He at least doesn't overrate them and treats like any one else the chiropractor and the science healer (secretly) and the veteran who draws a total disability allowance yet is on the police force, and even the prosperous-looking uplifter of society, knowing that each of them will look surprised when asked to pay for his services and that, so far as concerns *them*, he'll soon join the ranks of others never thought of

It is not with such as these that the doctor shows his best side. He feels far more at home with the ordinary, self-respecting people of modest means who don't expect, on this earth, to find green pastures provided for them with ten-cent cigars, a two-car garage, and a fish-fry in every dinner pail. They frankly say just what their circumstances are and what they can pay and when. For them, too, he can do no more than his best and only wishes it could be better, and cuts their bill in half or cancels it altogether. They never forget him but send him each year a note on the anniversary of the operation and, like enough, a pair of carpet slippers for Christmas which he can't use for he's in his boots till bedtime. But this he doesn't admit when making his acknowledgment, for he cherishes their remembrance—even their gratitude though pretending not to like it. And as a matter of experience, those who can least afford it are the ones among his patients most eager to make a prompt cash payment to him even though a large part of every hard-earned dollar goes to various unseen persons whom they are making rich, and to whom they feel obligated in no comparable way.

In his common sense discussion of the ever shifting manners, mores and morals of society before the undergraduates at Yale a generation ago, William Graham Sumner had much to say about a particular man who is never thought of and on whom the burden always falls. In the complexity and rivalry of human interests, he is the one who in the end always has to pay—even for the efforts of social reformers to make the world over.

"For once let us look up and consider his case, for the characteristic of all social doctors is that they fix their minds on some man or group of men whose circumstance appeals to the sympathies and imagination, and they plan remedies addressed to the particular trouble. They do not understand that all the parts of society hold together and that forces which are set in action act and react throughout the whole organism until an equilibrium is produced by a readjustment of all interests and rights. They therefore ignore entirely the source from which they must draw all the energy which they employ in their remedies, and they ignore all the effects on other members of society than the ones they have in view. They are always under the dominion of the superstition of government and forgetting that a government produces nothing at all they leave out of sight the first fact to be remembered in all social discussion—that the state cannot get a cent for any man without taking it from some other man, and this latter must be a man who has produced and saved it."

Now in the issue before us, if I may venture to paraphrase Sumner, everyone's sympathy, including that of reformer *A* and his friend *B* who stands financially behind him, lies with the self-respecting person *X* of modest income, who finds it difficult to meet the expense

of medical care in case of sudden illness or accident from some unpredictable and unpreventable cause. For the sake of *X*, this particular evil must be remedied by a statute which will determine, not what *A* and *B* might do for *X* themselves, for they would need no legislation for that, but what an intermediary *C* (in this instance the doctor) *must* do for him.

Now *X*, who has not yet been consulted, will be likely to say when he gets wind of it that, after all, he doubts whether he will ever need doctor *C*, even should he prefer him, when the time comes, to another medical man of his acquaintance. What is more, he is already burdened with more insurance and taxes than he can afford. He is already paying to support the local, state and an expanding federal board of health, for prisons to accommodate the rapidly increasing number of criminals, for institutions to house the even more rapidly increasing insane and feeble-minded, for hospitals to care for that organized group calling themselves "veterans," who may not increase in number but do in their demands, which amounts to the same thing.

So he and his neighbors conclude, in accordance with Sumner's social philosophy, that they as usual will again foot the bills, just as their common kind originally paid, little by little, all that now fills the coffers of *A*'s philanthropic friend *B* of the foundation which is backing the proposal. And from all one can learn, so far as the public purse is concerned, the old adage which likens it to holy water still holds true—those who have access to it help themselves.

Unfortunately, *X* is not always so sensible a fellow as to make a family friend, confidant and adviser of one or the other rival practitioners in his small town. And when the *X*'s gravitate to the city and shift from place to place when there, you and I know they are more apt to choose an abode convenient to a cinema and a drug-store than to a doctor. When a member of the family takes ill and fails to respond to the usual proprietary remedy, a neighbor is consulted who turns out to be a Christian Scientist, or another who suggests the particular chiropractor who for five dollars cured Uncle John of the flu at one sitting, or a third who has just seen in the morning paper the name of a perfectly swell professor who has just done something wonderful at the New Medical Center to a woman who swallowed her false teeth.

Acting on this suggestion, he is called on the telephone and asked if he won't please come immediately to Number so-and-so in Harlem to see a sick woman just in his line of work. No, they have no family doctor, so he asks if there is not a doctor in the neighborhood they can more conveniently and promptly call in. "Yes, there is a Dr. Jones just around the corner but we don't know him as we've only lived here nine months and never needed a doctor before, and anyhow he is only a house-to-house doctor and the case is so urgent we need a specialist at once and we can't afford to go to the hospital it's so expensive."

Our urban populations are largely composed of people of just this sort, and what's to be done to save them against themselves and keep them from "shopping around" as it's called? In this particular emergency one can't stop to theorize about systems of voluntary *versus* compulsory insurance, the chief burden of which would fall as usual on the average provident man of good habits, the matter must be attended to at once.

Ten chances to one there is nothing seriously wrong with this panicky woman, but the single chance can't be taken and the "swell professor" before he hangs up,

if he is the kind of man I know him to be, tells the person at the other end of the line he regrets he can't come himself but he will shortly have someone there to see what can be done. He has Dr. Jones's office called up to say there is a sick woman nearby and will he please see her when he conveniently can and say he comes at the "professor's" (God save the mark!) special request, and will he then take the case in charge or send her to a hospital as he thinks best.

Here the chances are also ten to one that the local doctor will prove capable and efficient, will promptly grasp the situation, know how to deal with it, and gain the confidence of the family and their friends. "Such a nice doctor, so scientific, and to think we've never known about him before! Why, he cured Mother's trouble in one visit and only charged two dollars though he's a great friend of the professor at the Medical Center whose name was in the paper." This, and a definite understanding that his back bills are to be paid before yours and mine, is the correct way to deal with the problem of the general practitioner, and it is more often followed than people believe.

But who is this house-to-house doctor so suddenly sprung upon us? He has supposedly gone out of business, pinched on one side by the public health officer and periodic life-extension examiners, and on the other side by what are called the scientific doctors including ourselves, the specialists in our respective hospitals. He has long been so far forgotten he should by this time be an extinct species. Indeed, it is authoritatively said that the automobile and the associated highways together with the present "set-up" of society have driven out the unmethodical, silk-hatted, bewhiskered, lovable and friendly general practitioner.

This scornful picture of the practising doctor shows lack of knowledge, besides being somewhat cruel. Whiskers and a silk hat don't make the man. Fashion makes the whiskers, and the boys in blue were as good soldiers for all their beards and Bull Durham as were those in khaki with their clean faces and fags—too many at that. Gillette and Henry Ford and the Dukes may through advertising and salesmanship change our appearance, our manner of getting about, and incite us to bad habits—incidentally with great profit to themselves. But even though his whiskers have gone with his tall hat, if he ever had one, and he comes in a cheap motor car instead of behind a horse, and nervously smokes too many cigarets, the general practitioner or family doctor is still with us and plays the same important role he always has.

For nine tenths of what he is called upon to do "the operating table and the microscope and the roentgen ray and the trained nurse and the mechanotherapeutist" are wholly unnecessary; and when they are needed he usually knows where to get at them. All he asks from his school is that, under teachers who know from experience rather than theory what his life work is to be, he may get the sort of well rounded training which will enable him to keep abreast of the changing times while in city or country, with dignity and propriety, he engages in the quiet art of healing.

Such are the men who represent the backbone of our profession and for each of them there are countless devoted patients and for each patient whole families whose voice in our discussions has not as yet been heard. And were it heard, it would be, in effect, what it always has been. "So long as I am well, I forget the doctor—and his bills which he often neglects to render, but he is always there in case of need except during a

vacation, something I notice he is more apt to prescribe for others than take himself."

It is to the self-sacrificing spirit of the sagacious practising doctor, not to the likes of us in this, that or the other line of special work, or the medical scientist, or the public health official that from the earliest times tribute has been paid.

Honour the physician because of the need thou hast of him, for the most High hath created him and in the sight of great men he shall be praised. All healing is from God. He hath created medicines out of the earth, whose virtue is come to the knowledge of men who shall thereby cure and allay pain.

So, in effect in the Book of Wisdom did the son of Sirach called Ecclesiasticus admonish the average man and potential patient, who differs no whit today from some nineteen centuries ago. He is no less gullible and superstitious, no less negligent and sinful, no less certain from time to time to betake himself to a physician, from whom he expects, and usually gets, not only understanding and sympathy but an honest opinion—accompanied by emphatic directions which it is to be hoped he will follow longer than he does his own good resolutions made each New Year's eve.

A remark, easily traceable to its source, has been often repeated to the effect that the family doctor will come to be replaced and crowded out by the local health officer. Preventive measures against the spread of disease are no new thing. The very word quarantine and its mystic forty days and forty nights is lost in the darkness of oriental history long before Hygeia, the daughter of Aesculapius, was worshiped as a health-protecting divinity. Even today when we are said to be more "scientific," our legal enactments relating to the public health still apply chiefly to the transmissible diseases, and the doctor has had much to do with bringing about the sanitary well-being of the community by hammering into the ears of reluctant legislators the necessity of permanent, non-political, state-paid officers whose enlarging powers become increasingly international in scope. What the doctor asks and expects of them is that the hard won ground he has gained be held and consolidated, so he can quietly go about his preparations to gain more, by pushing out another salient when all is ready for a concerted attack.

By the combined efforts of both groups, doctor and sanitary official the expectancy of life has been greatly prolonged—and will be more so before we are through. Yet while we point to this triumph, there are just so many more people who live longer only to be overtaken, the health official with the rest, by unforeseen and unpreventable accidents for which they seek the best surgeon they can find, or by some malady for which they demand the very best physician—like enough a highly trained specialist.

In short, for every disease from the beginning of time we have learned to escape by prevention, or to alleviate and even cure by drugs, there remain disorders beyond enumeration we cannot yet dodge because we don't know their cause. And even when this slowly and laboriously is determined for one malady after another, so that it may in turn be eliminated, would people only obey the laws of health, something else promptly crops up to take its place, for hitherto unsuspected derangements of our poor bodies are being detected and described almost daily.

Three fifths of the practice of medicine depends on common sense, a knowledge of people and of human reactions.—More than half of the remainder is tech-

nological and mechanical, the work of those medically trained artisans we call surgeons. What remains may be termed preventive, and this in bulk very properly and inevitably comes to be taken over by the state, though people, being what they are, find ways of evading a disagreeable statute as in the case of compulsory vaccination—intended for others but not themselves. Not everyone obeys the traffic light and every regulation breeds its jay-walkers and its racketeers.

Legislation and attempted coercion do not always accomplish what reformers anticipate. The country's recent quixotic experience with prohibition, the most important health measure ever sanctioned by a government, however well intentioned, probably set back rather than quickened that much to be desired goal of national temperance which by natural processes was slowly gaining ground. At great expense, a commission sat long and wearily on this subject, again without coming to a unanimous voice. And finally the mass of sober, obscure people of small means, who as usual were bearing the chief expense of enforcing a law which was breeding crime and disobedience, though inarticulate, at least could vote. So almost as one they decided, in spite of the lost ground and its disheartening confusion, to take a fresh start toward the slow cultivation of national restraint in the use of intoxicants. "The fallacy," said Sumner, "of all prohibitory, sumptuary and moral legislation to protect people against themselves is the same."

There has been much idle talk, too, regarding scientific medicine and the modern scientific doctor who with his ingenious appliances and mathematical exactitude has come to supplant the old-fashioned "practical" doctor. For hasn't he—or mostly his trained technicians—taken our blood pressure, our electrocardiograms, our basal metabolic rate, lumbar punctured us, ophthalmoscoped us, ventriculogramed us, x-rayed us from top to toe, studied under the microscope everything we can expect for him besides drawing off our blood for the same purpose, looked in all our orifices, tickled the soles of our feet, charted our calories, our calcium and phosphorus and nitrogen intake and output? It's peculiar after all that time and expense they can't seem to tell why Johnny has fits, perhaps blunt old Dr. Brown up country was right when he said that Johnny, during that attack of flu, had what *he* would call inflammation of the brain and the city doctors encephalitis lethargica—for which they charged more. But whatever it was called, he was sorry to say it couldn't have been prevented, nor was there much he or anyone else could do for it, and we'd just have to grin and bear it.

As a matter of fact, it will be a great shock to laymen to learn that a great part of what is called scientific medicine is a fetish and wholly unscientific. We have instruments of precision in increasing numbers with which we and our hospital assistants at untold expense make tests and take observations, the vast majority of which are but supplementary to, and as *nothing* compared with, the careful study of the patient by a keen observer using his eyes and ears and fingers and a few simple aids. The practice of medicine is an art and can never approach being a science even though it may adopt and use for its purposes certain instruments originally designed in the process of scientific research. In the case of Mary who got behind at school it has been found, to be sure, that her basal metabolic rate was minus five per cent, so she is now taking thyroid extract, and though it makes her nervous it's scientific-

cally correct, the doctor says and she must keep on with it.

Life is a competitive episode and, since capabilities differ and opportunities vary, some will prosper and some will not. This is sad, but it is futile to complain of these inequalities, for they are biologically inevitable. That all men are born free and equal is a noble sentiment, but in life's struggle experience shows they don't long remain so. "Liberty, equality and fraternity" is another republican shibboleth as impracticable and unattainable as the pole-star of Marxism in any social group much larger than the family and not always possible there. A somewhat more ancient idealism, expressed in another three words, may be found in the first chapter of Corinthians, and from that source the man who does his best to comfort and heal has inherited the belief that the greatest of the three is charity.

In spite of all the discouraging things they are permitted to learn about the units composing society, the doctor and the priest continue to have not only hope for but faith in their fellow men and expect them, in spite of their frailties, to be unselfish and honest till they prove themselves otherwise, whereas in trade, politics and the law, we are told, a man is primarily taken to be self-seeking until he proves the contrary. It may amount to the same thing in the end, but it at least shows a different approach, and it may partly explain why the doctor, compared with others, is known to be a poor business man. Thus, after all, may not be an unadmirable trait even though the dollar is taken to be the common measure of "success" in our present-day world, which looks scornfully on his financial incompetence.

I recall once being at 13 Norham Gardens in Oxford when the Regius Professor received a cable from a Maharaja in India. "Request you see son injured yesterday's polo game. God will pay the bills." The Regius promptly acted on this request, cabled reassurances to the Maharaja, and charged it up to the Almighty, already heavily in his debt. No, the doctor in the past has not been good at business and most of those who happen to possess that talent soon leave the profession for fields where they more properly belong.

Why he should refrain from forcible collection of his unpaid bills, why he does not patent some of his prescriptions, inventions and discoveries and make a fortune, why he should continue to counteract the spread of diseases he has painfully and at great educational expense learned how to diagnose and treat, why he should so strenuously oppose year after year the efforts of antivivisectionists and antivaccinationists with their Christian Science allies to cripple research and to annul statutes already on the books, knowing his calls would increase did they have their way, and why at the same time he should continue to work longer hours for less pay during a shorter life of activity than most people is an enigma to a hardheaded business man.

To be sure, business is now recognized as one of the professions in certain educational circles but whether this will elevate the ethics of business which is fundamentally competitive rather than fraternal, or whether it will undermine the code of medicine remains to be seen. With business goes advertising and there are few forms of it more profitable than the manufacture and sale of proprietary medicines over the same counter with candy, cosmetics and cigarets. Even science has unblushingly begun to spread her experimental discoveries in the raw before the public by fostering a lay

journal for the purpose. And since everyone is doing it, how long will the doctors continue as a class to resist? When they no longer do, and adopt the advertising methods of those parasites of the profession, the quack and the patent mediciner, God help the man of modest means and everyone else, whether below him or above him in the social scale, who may some day need a doctor.

He, the man of modest means, is at the mercy of an organized racket beside which "bootlegging" is as child's play, for that was a nocturnal game and this is played in the open. Lost somewhere in the Department of Agriculture is a Food and Drug Bureau which does its feeble best to control what is printed on the package advertisements. But only the Federal Trade Commission, which probably is composed of lawyers, could, if they saw fit, put a stop to the falsehoods the press continues to carry regarding the contents of the package. And when such a thing as an influenza epidemic comes along and every newspaper in the country is spread with advertisements of cheap proprietary sure-cures, what are the people to believe? If any embarrassing questions are asked, you may be certain that your congressman has already been instructed by a well organized lobby not to interfere with what is a profitable business.

The explanation of the doctor's seeming want of business acumen lies partly in the restraining influence of his time-honored precepts of conduct, partly in his preference to hold the respect of his own kind rather than of the financial world, and partly because inherently he's that kind of person else he wouldn't have gone into medicine in the first place. He's already done a great deal not only for the poor but for the man of modest means as well, and it is offensive to be told by a board of lay people that he's neglecting them.

I have been led to look up the records of my one hundred and fourteen medical classmates who after a three-year course were turned loose on the community now almost forty years ago. Some sixty per cent of them went promptly into general practice, and too many have broken down or died ahead of their patients. And though the survivors are modest fellows who don't like to talk even to a schoolmate about their measure of success, far less of any grudges they have against the world, what they do say runs something like this: "I'm in general practice in the small town where I was born, and proud of it. I've been sufficiently successful to raise and educate a family. I've served my country as a first lieutenant in time of war, and for a longer time my district as health commissioner in times of peace. I still retain my self-respect—with the exception of giving out liquor prescriptions. Distinctions none, not even having a baby named after me, which is unusual for a country doctor. Hobby my family, my patients, and a keen interest in world events."

Now to what I would chiefly call attention is that, of these graduates of forty years ago, who have lived in town or country the lives of general practitioners, a large percentage of them have served their communities in some public capacity, more often as health officer or as member of the local health board. But a basic medical education is no longer considered either desirable or necessary for the holders of such positions. The health officer must be a specialist among other specialists with which medicine is already overloaded.

Stirred by what may be accomplished in checking the spread of certain bacterial and protozoal diseases by a medically trained Gorgas or a Leonard Wood, in the

hope of perpetuating their species, a vast sum of money is set aside to educate separately and by a short cut those who are to take their places, all too often political appointees, which means for all of us a little higher tax. But when it comes to the ever recurring fight against adverse legislation relating to tuberculous cattle, to compulsory vaccination, and much else, it's again the doctor, personally known in the legislator's home and with no conceivable ax to grind, who must usually come to the defence of the paid local official lest ground be lost.

I don't for a moment mean to imply that we should go back, for there's no going back. I merely wish in fairness to recall what the practitioner in the past has done to safeguard public health and to point out that the chief burden of expense, when government enters in, always falls most heavily on the same man of modest means. And could he be heard, he would probably say: "Go slow with this proposal to insure me against those innumerable ills beyond control of the health officer. It will mean an elaborate organization of persons to make the system work, some form of racket will certainly grow out of it, comparable to the veteran racket, and even should the state take it over, it comes out of my pocket just the same."

And if the average man feels uneasy over the obligation to carry some additional insurance, the doctor feels even more so from his experience, at close hand, with the system of employer's liability insurance compulsory in certain states, which is a veritable hothouse of malingerers. At variable periods after a trifling injury a man reports at an ambulatory clinic or consults a doctor, sometimes a succession of doctors. Apart from his complaints, nothing is found wrong with him, but the case history is conscientiously taken and the results of the examination are recorded. Ere long the doctor finds himself summoned either by the man's lawyer or by the lawyers of an insurance company or both, to appear on a certain date with all notes of the case. It turns out that the man is suing his former employer for \$10,000 damages, knowing that back of him stands an insurance company that will probably settle the case rather than have it come to trial. The man almost certainly is a malingerer, but it's always possible to find someone willing for a certain sum to testify to a one hundred per cent disability because of that bump on the head from an electric fan two years ago.

Another form of legal racket which thrives on the insurance system at the expense of the profession is the rapidly spreading prevalence of malpractice suits, particularly against surgeons, for imaginary grievances sustained, more often than not, as the outcome of some operation done purely for charity. When one asks reputable lawyers about this, they merely shrug their shoulders, and against the evil the doctor is obliged heavily to insure himself and even then may not escape. Need we wonder at the mounting costs of medical care for honest people?

The impractical doctor at this juncture, after reading the reports of the Commission, ventures, half aloud, to suggest that the most effective and least burdensome form of voluntary health insurance would be for everyone to cut in half his (or her) annual expenditure for tobacco, which would not only leave more than enough in the family budget to pay all the costs of medical care in the family but would eliminate a multitude of incapacitating nervous disorders in the bargain. To this the economist scornfully replies that such a mad scheme would be ruinous to the tobacco planter, would under-

mine the huge superstructure of industry that he carries, would put an end to the alluring illustrations of smoking females which beautify the magazines and the countryside, and though there is not a cough in a car-load, one mustn't forget that the U S Treasury gets three cents on every package sold

Alongside this agitation regarding the expense of doctoring has gone a careful study of the prevailing trend of medical education. And as many of us here have been, or are still, actively engaged in teaching, we have all probably asked ourselves—even ventured to ask in faculty meetings—just what are we trying to make of our medical students? Departments multiply and every teacher, if he's what he should be, believes his own field to be of major importance, and there lurks in his breast the hope that some few of the leaders in each class before him may be lured into his special subject

From the first day, therefore, the prevailing system points toward that very thing which we now decry—overspecialization. And since science is now everywhere in the saddle and chief emphasis is laid upon it, the premedical sciences have first say and we tend more and more to carry great institutions of research as appendages to our schools, now manned in increasing numbers by teachers who have had no medical training, far less actual experience with the handling of patients.

I don't mean to say that this is all wrong and that there should be a *bouleversement*, I merely wish to point out that it makes the training of the doctor a long and highly expensive process and has had not a little to do with the expense of medical treatment. In actual fact, our schools no longer pretend that the degree of M D which students attain after four years prepares them for practice, we merely bring them to the point at which they must on their own initiative scramble for a hospital appointment where they hope to acquire what the school has neglected to give them—the training necessary to secure a license to practise.

With the degree, the school's responsibility—even interest—appears to end, and no school that I know of makes a consecutive and comparative study of its educational product. The surgeon in these later days who does not conscientiously follow up his cases to know what may be the ultimate outcome of the operations he performs is looked upon as an undependable routine, and one would suppose that every medical school would wish to know what was the end-result of its teaching. In my own school, at least, there is no such record beyond what is kept for social purposes by class secretaries, so it is impossible to learn, apart from the meagre information supplied by the national directory of physicians, how many men today compared with forty years ago are attracted into the sciences, immediately take up a specialty, turn to some salaried position in public health or one of the services, or largely go as of old into general practice.¹

There has been much lamentation about the disappearance of the family doctor but, as already shown, he's not often heard from and I am far from believing that he's a vanishing species, in spite of our scholastic

neglect of him in a system, which, by over-emphasis on research and prevention, rather than on diagnosis and treatment, gives him while an undergraduate a sense of inferiority which he hopes to overcome by going quickly into a small special field of surgery or medicine, however ill prepared.

And should the report of the Lowell Committee lead our class-A medical schools to realize that for the practical requirements of the family doctor there is too much early teaching without a hint at its application, and should it lead to such a modification of the course that the prospective patient and his malady are in the student's mind and before his eyes at least for an hour or two of every day for four years instead of a scant two, society would greatly benefit, and there would be less reason to complain of the high costs of doctoring. There is every reason to believe that out of this system there would emerge just as many capable investigators who choose to devote their lives to research, just as many who feel the urge to strive for an academic career in clinical medicine, and just as many future leaders in the public health service as we now produce by the curricular program of isolated compartments now in fashion.

The physiologist complains, probably with some justice, that the principles he has laboriously taught are not sufficiently dwelt upon at ward rounds, the pharmacologist, that therapeutics is neglected, the bacteriologist, that not enough stress is laid on allergy to which a new journal is entirely devoted, and now pressure is being brought to bear to have all bedside teaching permeated with emphasis laid on *prevention*, as though this were something novel to the clinician.

A rose by any other name is just as sweet, and there has been in common English usage for the past four hundred years what the doctor has known as prophylactic (to keep guard before), meaning precautionary, medicine. And it would be a slur on the students' intelligence for a surgeon, let us say, to point out, as he has been urged to do, that he wears rubber gloves to "prevent" infecting the patient, gives the anesthetic to "prevent" pain, removes the appendix to "prevent" peritonitis, and so on, *ad infinitum*. For his own part, he sits down and has a cup of tea to "prevent" fatigue and then to "prevent" irritation keeps away from the faculty meeting where the great importance of preventive medicine will again be pointed out to him. Like many another catchword—"reconstruction," for example, which was on everyone's lips after the War—"prevention" can be very much overworked. There is only one ultimate and effectual preventive for the maladies to which flesh is heir, and that is death.

So the bewildered and harassed clinical teacher, be he physician or surgeon, can only say in rejoinder that it is futile to talk about preventing something one does not yet know how to recognize, that the short time at his disposal hardly suffices to teach the student how first to detect some few of the more common diseases and their complications, that in coming to a diagnosis the history and the physical examination of the patient are the important things and the findings of the laboratory purely subsidiary, that with more than half of the persons who have some ailment to complain of it's impossible to tell quite what is wrong so that recourse must be had to encouragement and symptomatic treatment, that the knowledge of how to deal with the sick comes only with long experience, that the man and his mental reactions to his troubles must be treated as well as the disorder itself even when its nature is clearly

¹ It is quite possible that the tendency toward specialization has been considerably overdrawn. Just because a practitioner limits himself largely to internal medicine, to surgery or to obstetrics does not justify classifying him as a specialist. Every general practitioner comes to be known in his community and recognized by his fellows as possessing unusual skill, due to experience and good luck in a certain type of cases. Hence he is apt to be called in consultation for let us say the pneumonias, the fractures or the eclampsias of his community. Because of this altogether natural process of selection even the practitioner unless he happens to be covering his district single handed comes inevitably to particularize in his work with the passage of time.

recognized, in short, that the bearing of all that the student has learned in his preclinical courses, apart from a training in precision and accuracy, which he might have gotten as well in the clinic, has unfortunately nothing much to do with the vast majority of problems with which he will be confronted when he gets into practice.

Whether we have temporarily overstressed science and research in medical education and let it come to enslave us is not for anyone to say. If it has, the day will arrive when of itself the pendulum will swing and there will be a corrective reaction, for there usually is to whatever we overdo. In France, as all know, the traditional method of instruction has been all too much the other way about, for there it has long been the custom promptly to souse the matriculant in the sea of disease from which he must flounder his way out. This he has managed somehow to do. But now the pendulum swings and there has been, as here, a much discussed movement to reorganize medical teaching to meet the demands of the changing times. Not only is it proposed to add an extra obligatory year to the medical course, making six to qualify for general practice, but two years more than that will be required of those who would take up a specialty, and when it comes to those who aspire to be operating surgeons—so dangerous to *ses concitoyens*—an additional four years.

Even this is not all. The matter has reached and been ardently discussed in the Chamber of Deputies, where the desirability of more scholarship and less science for the practising doctor has been warmly advocated. A "back to the humanities" movement has arisen which would oblige the prospective medical student before his matriculation not only to be qualified in preliminary physics, chemistry and the natural sciences, but since all good things are of Hellenic origin, he must know Greek and Latin as well!

There meanwhile has been much pointing to Sir Thomas Browne and to Rabelais and to the Linacres of the profession, as though many of us could hope to be humanists of their sort any more than be productive investigators in the fields of present-day medical science. And while it is a subject on which a surgeon, in view of his illiterate ancestry and addiction for the vernacular, is scarcely entitled to speak, he can at least be permitted to admire and envy scholarship in his medical colleagues—even as did Pare.

Professor S. E. Morison, the historian, has called my attention to the fact that at Harvard, and probably at other universities as well, medical *Questiones* in past years were publicly debated in Latin at Commencement. In 1660 *An Motus sanguinis sit Circularis?* (Is there a circulation of blood?) In 1678 *An hep̄ sanguifcet?* (Does the liver make blood?) In 1687 *An Curatio per pulverem sympatheticum sit licita?* (Can a cure be effected by sympathetic powder?) In 1690 *An Morbi sint Contagiosi?* (Are diseases contagious?)—and so on, showing that seventeenth century laymen were interested in matters concerning which contemporary doctors, trained by the apprentice system—and not a bad system at that—were inclined to disagree.

And even at the present time, I believe that the translation of a page both of Greek and of Latin is still required of everyone who would become Fellow of the Royal College of Physicians and thereby qualify as a consultant—for how else could he use the pharmacopeia and write prescriptions, much less read the *De Motu Cordis* in the original! I was once told by Sir Henry

Head that, in 1900 when both he and Robert Bridges had gone up for their fellowship examination together, they chanced to meet on leaving the hall and he asked Bridges how he had made out with his translations. Bridges replied that the stupid examiners hadn't stated what language they wanted the pages turned into so he had translated the Latin page into Greek and the Greek into Latin.

There always has been and always will be a certain proportion of scholars and humanists in medicine—men like William Sydney Thayer, who has so recently left us—just as there will be a smattering of scientists and artists and musicians, even novelists, poets, and an occasional statesman like Clemenceau—and it will be a sad day when we all come to be cut from precisely the same piece of educational cloth. Some may happen to take their scholarship, as others pursue their hobbies, seriously, even professionally, but the curriculum has less to do with it than most of us pretend to believe.

Where now do we stand with the case before us? Sir James Paget once remarked that, so far as he could learn, he was the only person who had ever recovered from double pneumonia after nine different consultants had been called in on the case. Dame Medicine finds herself just now in a similar plight. Considering her age, she has been unusually active these past few decades and, much to her embarrassment, finds herself as "news" and altogether too much in the limelight. Being a retiring person who prefers simplicity, she has begun to show the strain of justifying the luxurious Babylonian hospitals and laboratories people of inflationary tendencies have insisted on building for her to use and give her whole time to.

Meanwhile, she has been somewhat worried by the fact that altogether too many of her offspring under the influence of the saxophone and the speak-easy have gone distinctly modern, become citified, ticker-minded, and gotten out of hand. While she has tried to console herself with the thought that this was only a temporary postbellum phase, which seemed to affect other people's children the same way, her personal responsibility in the matter was put in the hands of a commission of nineteen eminent persons for investigation. After giving them what help she could and hoping an explanation for the existing instability of the world would be found, she set about her daily tasks with customary energy and apparent good spirits.

But the real trouble began after someone persuaded her five years ago, when she was feeling sturdy enough, to submit to a physical examination—in fact, considering her recently recognized social importance, her countless dependents and retainers, not to speak of her immediate family, she should have done so of her own accord every six months at least. Why, with all her hard work these past years she probably has hypertension or something worse, which should have been taken in time!

In view of her long neglect, it must now be done thoroughly and scientifically—family, marital and past history, social environment and habits, dreams and complexes, just to start off with. High blood pressure indeed! Why, one couldn't prick or prod her anywhere without finding a sore spot. Whatever the cost, she must take a room in the medical center for a more detailed study.

With misgivings, to this opinion she reluctantly submits. A board of fifty consultants composed of experts and specialists of every sort is called in. They in turn appoint others to assemble the data necessary for a

diagnosis. Surveys are made, statistics are gathered and graphs are plotted. Twice a year to discuss and correlate the findings, the chief consultants meet, meanwhile issuing reports of progress, and being scientific rather than practical doctors, the patient is not only allowed, but encouraged, to read these protocols, and she begins to feel very shaky about herself.

It becomes perfectly evident that the family, after a fair start, has somewhere acquired a bad gene—possibly from that fellow Paracelsus. And the poor old thing has had altogether too many offspring, most of them turned loose with no sort of control. These past few months, she's not only been losing weight but showing signs of irritability and certainly should be psychoanalyzed. This so far she has flatly refused, saying it's nasty, so we must keep her in bed a while longer, perhaps a wheel chair for an hour in the afternoons, while further studies of these alarming symptoms are made.

One of her doctor sons, who for propriety's sake has been permitted to sit in with the consulting board as an observer, occasionally slips into the sickroom, pats her on the back and says "Never mind, Mother, buck up, it will soon be over, there's not much more they can find to do, and I'm sure it's not so bad as they think. Even if it is, you've had a good fling these past forty years and the boys have asked me to say how sorry we all are not to have been a greater credit to you. But you simply *must* stop reading your clinical history and watching your temperature chart or you'll get neurasthenic. What you chiefly need is a good night's sleep."

Finally the data are all prepared, and, as usual, there is want of agreement on the diagnosis and much less, consequently, on what's to be done. The gloomy majority feel that it's a deep-seated disease and probably incurable. Birth control and a better distribution of her activities on thinly populated places might be worth trying, but before it's too late, she certainly should get insured. The more cheerful minority, who know her better, think it's just a case of nerves brought on by the times, by overwork and needless worry about some of her unruly children. One or two others, disagreeing with both of these opinions, insist that, nothing venture nothing have, it's better to be bold and operate at once, as it's the only possible way to make certain there's nothing in the pelvis—and if there isn't, there likely enough won't be.

As a compromise, someone is told off to break it to the poor old thing, considerably shattered by this time and a shadow of her former confident self, that though there is something indeterminate which is radically wrong, she may temporarily leave the clinic, on payment of the bill—now amounting to several millions—which she will find at the main office. However, if she doesn't change her general habits and manner of life, which make her a menace to society, and adjust herself to what is now an industrial world dominated by business and insurance, she'll be obliged to return for an exploratory operation, and that will cost a pretty penny.

Whereupon, with thanks for their efforts on her behalf, she ventures to suggest that everyone seems to be suffering just now from a sense of insecurity and indecision and it might be as well to wait until we pull ourselves out of this slough of depression and see just where we persons of modest means all stand before deciding on anything radical. She calls to mind what Galsworthy once said the *statu quo* is of all things most likely to depart, the millennium, of all things, least likely to arrive. There might chance to be a war

or another influenza epidemic when we would need all the doctors we have and more, and all the empty hospital beds would quickly refill.

There are two sides to every question and inability to see both constitutes the fundamental weakness of all theories and particularly those relating to the biologic and social sciences. This failure even invades what is supposed to be the most exact of all sciences, astrophysics, which supposedly deals with great abstracts. But one can approach an abstract from either side, and depending on different views of cosmogeny, the universe is either expanding at a terrifying rate or contracting no less rapidly. If both views are correct, it must therefore pulsate like a macrocosmic heart.

But however this may be, those who deal with the science of society deal with something that actually *does* pulsate with so short a time cycle that conditions almost from year to year are never quite the same, so that our theories of today are likely to need modifying tomorrow. What this puzzled world needs perhaps is more study of the past, fewer commissions and surveys of the present, and a greater number of philosophically nunded, self-supporting and law-abiding persons who can see all round their particular problem and independently devote themselves to it as do most doctors and as did the little knife-maker in Langres.

And should the doctor, in moments of discouragement about the shortcomings of his own tribe, now so thoroughly ventilated as to make those he is most anxious to help have misgivings about him, need like other people a timely word of comfort, he can remember that, whatever the doctor of the future may come to be, it has been said not long ago of the doctor of his particular time—and with some small measure of truth by one who had good reason to know him well—that

He is the flower (such as it is) of our civilization, and when that stage of man is done with, and only remembered to be marveled at in history, he will be thought to have shared as little as any in the defects of the period, and most notably exhibited the virtues of the race. Generosity he has, such as is possible to those who practise an art, never to those who drive a trade; discretion, tested by a hundred secrets, tact, tried in a thousand embarrassments, and what are more important, Heracleian cheerfulness and courage. So it is that he brings air and cheer into the sickroom and often enough, though not so often as he wishes, brings healing.

Discarding Useless Remedies—The problem of discarding useless remedies is still with us, because new remedies are thrust on the medical market by drug manufacturers in increasing numbers. Many drug manufacturers in various parts of the world are now actively engaged in investigating new compounds. These investigations are expensive, and the manufacturer rightly looks to recoup himself for the expense by the profits on a new drug, if he can put it successfully on the market. Until we know more about the relations between chemical constitution and physiological action, this type of research must remain largely as a gamble so far as concerns the discovery of a successful remedy. The testing of a new drug on the therapeutic side has often been perfunctory and done by medical men who have neither the training nor the facilities for arriving at a correct estimate of therapeutic value. This difficulty has recently been at least partly removed by the institution of the Therapeutic Trials Committee of the Medical Research Council. A manufacturer can now submit a new drug for the consideration of this committee and the committee can, if it believes that the pharmacological indications justify a therapeutic trial, make arrangements for a scientific and thorough investigation of the therapeutic merits of the drug—Gunn, J. A. Remarks on the Outlook of Research in Therapeutics, *Brit. M. J.* 2 391 (Aug. 27) 1932.

FRACTURES OF THE HUMERUS

STATISTICS AND TREATMENT IN FIVE HUNDRED
CONSECUTIVE CASES

WILLIAM R. CUBBINS, M.D.

Associate Professor of Surgery Northwestern University Medical School
Attending Physician Cook County Hospital

AND

CARLO S. SCUDERI, M.D.

Instructor of Surgery University of Illinois College of Medicine
Fracture Resident Cook County Hospital
CHICAGO

During the period of thirty-two months from September, 1927, to April, 1930, 500 patients with fractures of the humerus were admitted and treated at the Cook County Hospital of Chicago. This great volume of material afforded an excellent opportunity for careful study, and at the same time we were able to draw definite conclusions as to the frequency of complications, the method of treating both simple and complicated fractures, and the end-results of our labor.

INCIDENCE

Fractures of the humerus compose about 5 per cent of all the fractures of the body. Stimson gives the figure at 4 per cent, von Bruns at 5 per cent, and Speed at 5.7 per cent.

In our series 233 of the fractures, or 46.6 per cent, occurred in the right arm while 255, or 51 per cent, were in the left. Twelve, or 2.4 per cent, were unclassified.

Three hundred and sixty-five, or 73 per cent, of the fractures were in males, while the remaining 135, or 27 per cent, were in females. This relationship corresponds with that reported by Gurlt, who gave the figures many years ago at 3 to 1.

The average age of all the patients with fractures of the humerus was 36.2 years. The youngest patient was 4 months of age and the oldest, 84 years.

Only one case of fracture of the anatomic neck of the humerus was encountered. This patient was 34 years of age.

Fractures between the anatomic and the surgical neck were classed as pertuberculous. These were six in number, or 1.2 per cent. The average age of the patients was 37 years.

Fractures of the surgical neck composed almost one third of all fractures of the humerus. One hundred and fifty-four were of this type or 30.8 per cent. One is surprised, off hand, at such a figure. The average age of these patients was 50.3 years, 90.8 per cent being over 16.

Not one case of fracture of the lesser tuberosity occurred during the thirty-two months. The greater tuberosity was fractured in twenty-eight cases or 5.6 per cent, ten or 35.7 per cent were associated with dislocations of the head of the humerus. The average age of the patients was 49.1 years, all of the patients being over 16. Speed and Stimson state that few cases of fracture of the greater tuberosity occur without dislocation of the head of the humerus, but we found this true in only one of every three cases of fracture. (The senior author is somewhat skeptical about this figure.)

Epiphyseal separation, partial or complete, occurred in nine cases or 1.8 per cent. This included both the upper and the lower epiphysis. The average age of the patients was 11.3 years.

There were 152 fractures of the shaft of the humerus, only 2 less than those of the surgical neck. These composed 30.4 per cent of the total. Twenty-two, or 4.4 per cent, were in the upper third, 109, or 21.8 per cent, in the middle third, and 21, or 4.2 per cent, in the lower third.

The average ages of the patients with fractures of the shaft of the humerus are given in table 1.

The apparent paradoxical relation between the decreasing ages and increasing percentage is correct, as many of the fractures of the lower third of the shaft occurred in patients between 17 and 30 years of age.

Von Bergmann states that fractures between the attachment of the pectoralis major muscle and the origin of the supinator longus muscle are the most frequent fractures of the humerus, but he quotes no figure. Riethus states that 53 per cent of all fractures of

TABLE 1—Age Incidence

Position	Age Years	Percentage Over 16 Years
Upper third	43.3	77.3
Middle third	36.3	81.6
Lower third	33.0	94.7

the humerus are in the shaft. Perhaps this large discrepancy as compared to our figures is a question of classification.

There were eighty-three supracondylar fractures, or 16.6 per cent. The average age of the patients was 27.6 years. This apparently high average age was produced because several of the patients were well over 65. A truer conception is had when one finds that 67.5 per cent of the patients were under 16.

Dicondylar fractures numbered nine, or 1.8 per cent. The average age of the patients was 16.8 years, 55.6 per cent being under 16.

There were fifty-eight condylar fractures, or 11.6 per cent. This includes one or the other condyle. The average age of the patients was 13.8 years, 86 per cent were under 16. Stimson gave the statistics in table 2 on forty-eight fractures of the humerus in the vicinity of the elbow joint.

TABLE 2—Fractures of the Humerus (Stimson)

Location	Cases
Supracondylar	8
Intercondylar	7
External condyle	15
Internal condyle	10
Internal epicondyle	8

When analyzed, the complications produced an interesting study. As complications always mean increased disability and prolonged treatment frequently associated with mutual sorrow to both the patient and the physician, they must be considered in a serious light.

Nonunion and delayed union, the most common complications, together occurred in fifteen cases, or in 3 per cent of all fractures of the humerus. It became necessary to classify these complications as one, because after a primary failure to unite the patient insisted that something be done immediately for economic reasons, so most of them were operated on prior to the four month period which separates nonunion from delayed union. It is interesting to know that all these fractures were of the middle third of the shaft. Transverse fractures were the greatest offenders, while when there were poor comminutions of the fragments, an early, firm, bony union took place.

In von Bruns' statistics of 1,274 cases of ununited fractures, there were 376 fractures of the humerus. Of 681 authentic cases of pseudarthrosis, 226 were of the humerus (33 per cent).

The combined statistics of Codivilla, Cuneo and Chutro show that fractures of the humerus result in 32 per cent of all cases of pseudarthrosis, while the

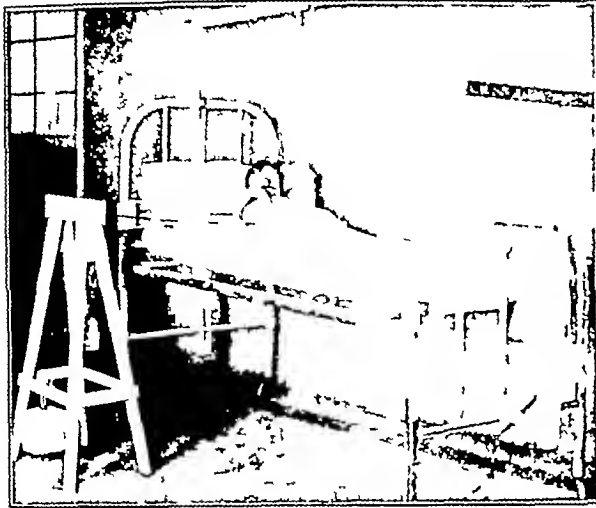

Fig 1—The ideal method of primary immobilization in fractures of the shaft or of the surgical neck of the humerus with displacement. Usually from 5 to 8 pounds is sufficient to produce a reduction. Later even as little as 2½ pounds of weight will hold the fragments in line and prevent unnecessary fibrosis of the elbow joint.

tibias, which are considered by many as the most common location of pseudarthrosis, are involved in only 13 per cent.

Radial palsies were the second most common complication. Fourteen cases were recorded, giving a proportion of 2.8 per cent of all fractures of the humerus. All these cases followed fractures of the middle third of the humerus. No cases of secondary involvement of the nerves were recorded.

When one compares the fractures of the middle third of the humerus with the radial palsies, one finds that 12.8 per cent, or about one of every eight, is associated with wrist drop. This complication was produced most commonly following spiral rather than comminuted fractures. All of our cases of radial palsy were found within two to twenty-four hours after the accident.

Surgeons distinguish anatomically between the cases in which continuity of the nerve is retained and those in which it is lost. The latter are rare. In seventy-nine cases, von Bruns found only three of this sort. In five cases in which the patients were operated on by the senior author, complete severance was never found.

Scudder and Paul reported radial palsy in 86, or 7.2 per cent, of 1,185 cases of fracture of the humerus. Von Bruns' collection of 886 cases in 1886 showed fracture of the shaft of the humerus in 53 per cent, fracture of the proximal end in 22.2 per cent and fracture of the distal third in 24.7 per cent. The latter figures of Riethus on 319 cases showed fracture of the middle portion of the humerus in 33.6 per cent, fracture of the proximal end in 35.4 per cent and fracture of the distal end in 31 per cent. In his series of cases, musculospiral paralysis occurred in 4.1 per cent. Vennat reports 13 cases in children, in 3 of which complete division of the nerve was found.

Compound fractures occurred in five cases, or 1 per cent.

Malunion (clinical, not roentgenographic, diagnosis) occurred in three cases.

Osteomyelitis developed in two cases. In one the fracture was caused by a gunshot wound, and in the other an extensive soft tissue trauma and a spiral comminuted fracture were sustained during an automobile accident.

There were two pathologic fractures. One was caused by a metastatic carcinoma of the stomach, the other, by a benign bone cyst in a boy of 5 years. Following the fracture there was a good union in the second case, and when the boy was seen eighteen months after the original accident the humerus was firm, giving no trouble, but roentgen examination showed that the cyst was about the same size.

In one case excessive callus developed following refracture of the middle third of the humerus two months after the original accident. The mass was 7 cm in diameter at the time of the patient's discharge. There was a good union, with absolutely no signs of radial palsy. He was seen three months later, and the mass had decreased to 4 cm.

TREATMENT

The treatment of fractures of the humerus varies considerably in different institutions, and even among physicians in the same clinic. The following methods have been used by us with uniformly good results.

The only patient with fracture of the anatomic neck of the humerus who came under our observation was treated in traction for three weeks and then in a Middelorf triangle for two more weeks with a good end-result anatomically and clinically.

Buchanan believes that excision of the head of the humerus is the best method of treatment. He cites fourteen cases from the literature in which two results were excellent, six good and one moderately good. There were two deaths. Although our experience has

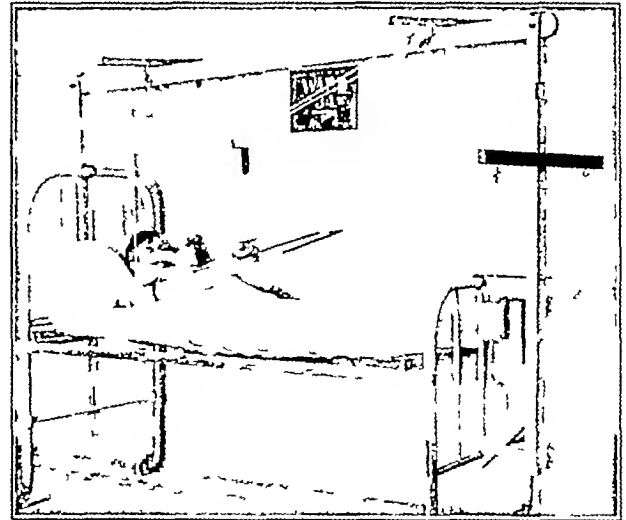

Fig 2—Occasionally it becomes necessary to bring the arm parallel to the body to get the best apposition of the fragments. This position is rarely required but should be kept in mind.

been limited to only one case, we believe that the operative removal of the fractured fragment is too radical and should be used in cases in which treatment by the conservative methods has been unsuccessful.

Unless a fracture of the surgical neck of the humerus is of the subperiosteal or impacted type in good position, which we have found not to be common, we

prefer treating the patients in traction for from three to four weeks with from 3 to 8 pounds. The weight and time depend on the size of the patient, the displacement, the age and the clinical observations in the case. The weight is decreased as the muscle spasm diminishes, as soon as sufficient callus forms to prevent recurrence of the deformity, the patient is placed in some form of ambulatory immobilization such as the airplane splint, Middeldorpf's triangle or a Velpeau bandage. After about two weeks of this immobilization, which we term secondary (the traction in a Thomas splint being called the primary immobilization), the arm is put in a sling, and guarded use is encouraged. We consider the sling the tertiary form of immobilization. Patients with subperiosteal or impacted fractures in good position may be treated by the secondary form of immobilization immediately.

We have found it of great advantage, with a decreased length of disability, to treat fractures of the surgical neck and the upper third of the humerus by the double Buck extension, one holding the forearm at right angles to the arm and the other pulling the humerus laterally at right angles to the axis of the body. These patients, even after four weeks of immobilization, may use their arms the first day the traction is removed, so good is their elbow, shoulder and wrist motion. However, in cases of fracture of the shaft of the humerus with bad displacement of the fragments, or in those of fracture of the middle and lower thirds of the humerus which are not easily held in position, straight arm extension should be used even at the expense of mobility of the elbow which may require weeks to return.

The general plan of treatment for fractures of the shaft follows rather closely the methods just discussed, the immobilization being slightly longer because the union does not occur as quickly.

In children, greenstick fractures are treated by the use of plaster, frequently in the form of a Velpeau bandage.

Fig 3—An airplane splint made of plaster with a metal reinforcement running up the thorax to the axillae—along the arm to the elbow and then down to the crest of the ilium. The cast runs low enough to be firmly fixed on the crest of the ilium. The parts at the shoulders, elbow and pelvis are padded with saddle felt to prevent pressure on the bony prominences. This is occasionally used as a primary form of immobilization but usually as a secondary method of fixation after the patient has been taken out of traction.

Physical therapy is always used as soon as the callus appears to be clinically substantial. Diathermy may be used on the muscles while in traction to great advantage, decreasing the period of disability. However, when the quantity of material is too scanty or the institution is not free with funds, the foregoing luxury is often done without.

We have been unable to hold complete fractures of the shaft, either oblique or transverse, in satisfactory position by the use of any ambulatory method, except in a few selected cases. In fact, the results in our hands were so poor compared to the extension method in bed that we have practically abandoned it as a form of primary immobilization. As a form of secondary splinting, after the callus and alignment have been satisfactorily produced by the recumbent method, the

Fig 4—A modified Velpeau bandage of plaster applied over a sling used as an excellent postoperative form of immobilization for fractures of the humerus. Sheet wadding is first applied so as to cover all bony points, then only three rolls of 6 inch plaster, 10 feet long are used, thereby giving the cast a pliable consistency. It is comfortable to lie on. More plaster than this makes it too rigid for absolute comfort.

ambulatory methods are ideal (airplane splints, Robert Jones splint, Middeldorpf's triangle or plaster).

Fractures of the greater tuberosity numbered twenty-eight, ten being associated with dislocations. All the patients were treated conservatively. One case later required operative removal because of restricted abduction. After reduction, nearly all of the patients had good approximation of the detached fragment if the humerus was abducted to 45 degrees. Few cases required 90 degrees abduction. We were unable to confirm the opinion of some investigators that the evulsed fragment is always pulled away to the extent of maximum abduction of the humerus. Much to our amusement, several of the fractures remained in excellent position after the dislocation had been reduced by merely immobilizing the humerus along the thorax in a Velpeau bandage of plaster. To us, this was a revelation, after hearing so much talk to the contrary from some of our colleagues.

Supracondylar fractures were uniformly well reduced if seen early, by first hyperextending the elbow and pulling the distal fragment down to its normal position, and then correcting the posterior displacement and bringing the forearm into acute flexion and complete supination. This position is then held either by adhesive strips, or by a posterior molded splint for from fourteen to twenty-one days, followed by gradual extension and passive motion. Passive motion and later active motion are used, depending on the age of the patient and the clinical observations in the case.

Occasionally, fractures of the condyles or epicondyles require operative treatment owing to persistent displacement. We prefer catgut suture to the periosteum in young patients, while in older patients a screw is frequently inserted and later removed.

Of the 500 patients, 472, or 94.4 per cent, were treated with the closed methods. Operations were performed in all cases in which the conservative methods had not obtained the desired result. It was necessary to operate in only twenty-eight cases. The indication and the type of operation are listed in table 3.

TABLE 3—Indications and Type of Operation in Twenty-Eight Cases

Indication	Cases

One will readily note the apparent lack of the use of foreign bodies as forms of internal fixation. We have found by experience that they frequently lead to trouble, and unless they are removed soon after they have completed their cycle of use they many times give rise to trouble years later.

Until a year ago, when performing open reduction on the shaft of the humerus, we were accustomed to strip the periosteum loose from the humerus and quickly angulate the ends of the bone through the wound. We did this readily by the use of Lane elevators, being careful of the radial nerve, and staying close to the bone. After the insertion of an intra-

Fig 5—A a modified Middelдорpf triangle made of boxwood held together by adhesive tape and then padded so as to not become uncomfortable. We never make it more than 5 inches on a side, and usually it is made as an isosceles triangle. After it is fitted into the axilla it is snugly wrapped with bias army style bandage. B after the triangle has been firmly applied a sling is worn. The patient can judiciously use the elbow, wrist and fingers while the fragments are held practically immobile, especially if the fracture is of the upper third of the humerus.

medullary bone peg, it was found that the fragments had too much range of motion in spite of the internal form of fixation. On one occasion we carefully preserved the posterior periosteum instead of tearing it in the usual manner. After the insertion of the peg, we found that by pulling the elbow forward the posterior periosteum acted like a taut rubber band, the more

tension that was placed on it, the more firmly was the fracture immobilized. This method was so highly satisfactory that we have used it in every case in which the conditions have been favorable. After the wound has been closed and the dressings applied, a Velpeau bandage of plaster is applied, and the immobilization is excellent. We are offering this trick to the medical profession, hoping that those who are having the same difficulty with immobilization by internal fixation as we had will find it of value.

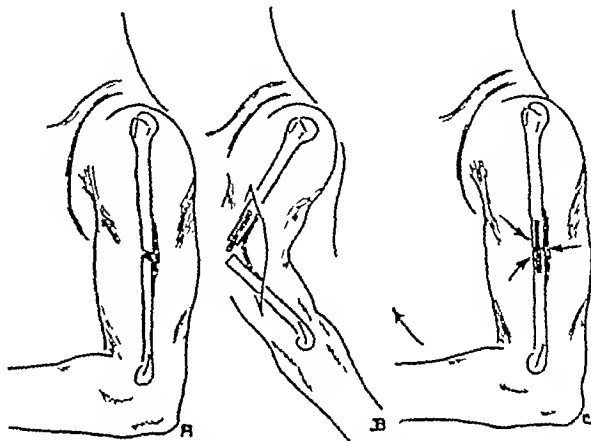

Fig 6—A a transverse fracture of the middle third of the humerus with the posterior periosteum carefully preserved so as to be used later as a splint. B the fragments have been angulated out of the wound. The posterior periosteum has been preserved and the autogenous intramedullary peg inserted. C the fragments have been straightened into their normal position and the intramedullary peg has been pushed equally into the two fragments. The forearm has been flexed to a right angle bringing the fractured ends snugly against the posterior periosteum, which acts as a splint, preventing any possible posterior angulation. The arm is then immobilized in a Velpeau bandage of plaster of paris.

CONCLUSIONS

- 1 Fractures of the upper two thirds of the humerus are more common in adults, while those of the lower third are more common in children.
- 2 Fractures of the surgical neck of the humerus are more numerous than any other one type of fracture of the humerus (in our series).
- 3 Open reduction was required in one of every eighteen cases.
- 4 Nonunion and delayed union occurred in one of every thirty-three cases.
- 5 Radial palsy was found in one of every thirty-four cases of fracture of the humerus, or in one of every eight cases of fracture of the middle third of the humerus.
- 6 Complications of some type occurred in one of every nine cases of all fractures of the humerus.
- 7 Fractures of the surgical neck and the shaft of the humerus were best treated by primary immobilization, or traction, for from three to four weeks, secondary immobilization with Middelдорpf's triangle, an airplane splint or a Velpeau bandage for two weeks, tertiary immobilization with a sling for one week, and total immobilization for from six to seven weeks.
- 8 Fractures of the greater tuberosity do not require 90 degrees of abduction, except in rare cases.
- 9 Supracondylar fractures give the best end-result if treated in maximum flexion and complete supination.
- 10 Foreign bodies should be avoided as much as possible in open reduction.
- 11 The value of preserving the posterior periosteum in open reductions for fractures of the shaft of the humerus should be kept in mind.

THE HIGHER CARBOHYDRATE DIET METHOD IN DIABETES MELLITUS

ANALYSIS OF ONE THOUSAND AND FIVE CASES

P. A. GRAY, MD

AND

W. D. SANSUM, MD

SANTA BARBARA, CALIF.

During the past seven years we have observed the effects of diets which, so far as their carbohydrate content is concerned, are more liberal than the so-called classic or strict diabetic diets. At first, the interest of one of us (W. D. S.) in this type of diet was (1) to learn how much carbohydrate could be substituted for fat in the diet of a diabetic patient taking a constant dose of insulin, without producing glycosuria, and (2) to perfect the older diabetic diets from a nutritional standpoint. Any one who has prescribed the older diets will recognize their nutritional deficiencies. Sansum, Blatherwick and Bowden¹ reported in 1926 that they had "been able to substitute more than an equal number of grams of carbohydrate for the fat omitted." Subsequently it was observed that even greater liberality as concerns carbohydrate could be permitted the diabetic patient without apparent detriment. The improvement of the new diets over those necessary in the preinsulin era is obvious: an increased carbohydrate ratio makes possible a greater amount and variety of minerals and vitamins, and "balances" the diet to a more nearly normal, or nondiabetic, standard. Clinical experience has led us to believe that it is not only possible and practical to feed the diabetic patient a diet that approaches normal, or nondiabetic proportions as regards the carbohydrate-fat ratio, but that it is advantageous to do so. The present study was undertaken to ascertain whether or not objective evidence obtained from the case records would substantiate this impression.

Our material consists of 1,055 cases of glycosuria admitted to the metabolic division of the Santa Barbara Cottage Hospital and to the Sansum Clinic between Jan. 1, 1925, and Jan. 1, 1932. Of these patients, who were for the most part private white patients of the upper middle class, 1,005 were considered to have true diabetes mellitus, 31 potential diabetes, and 7 renal glycosuria. The material is equally divided between the sexes, there being 504 males and 501 females. The distribution according to age is 9 in the first decade, 74 in the second, 71 in the third, 67 in the fourth, 135 in the fifth, 273 in the sixth, 281 in the seventh, 83 in the eighth and 12 in the ninth. As might be expected, over half (55.1 per cent) of all cases occurred during the sixth and seventh decades. A familial incidence was noted in the histories of 239 cases (23.9 per cent).

Ninety-five patients are known to have died prior to Jan. 1, 1932, and in eighty-one of these cases the cause of death is accurately known. Table 1 lists the cause of death and the average age at death of the patients in each group. Uncomplicated coma has not been a cause of death since 1925. The ages of the two patients who died in that year and in whom no other cause for death except coma could be found were 8 and 15 years.

From the Santa Barbara Cottage Hospital and the Sansum Clinic.

The shift from coma to arteriosclerosis as the chief cause of death among diabetic patients has been a conspicuous feature of recent mortality statistics (Joslin,² Warren,³ Leutengegger,⁴ and others). Arteriosclerosis appears as the chief single cause of deaths (40 per cent) in our series. The average age at death in this group was 63 years.

ARTERIOSCLEROSIS

The distribution of arteriosclerosis among these cases has been computed by decades and for the duration of diabetes. All three of the usual criteria for recognizing the presence of arteriosclerosis have been used: (1) pathologic evidence from postmortem examination of fatal cases, (2) roentgen evidence of calcification of arteries, and (3) clinical evidence of visible changes in the retinal vessels, palpable thickening of peripheral vessels and persistent hypertension. Since all the fatal cases are included in this study,⁵ it is weighted in favor of arteriosclerosis. An increasing incidence of arteriosclerosis by decades is apparent. Only two cases were noted before the fourth decade. From there on, the increase is definite and constant: each decade until 100 per cent is reached in the ninth decade. No comparable rate of increase, however, is noted in the groups representing the duration of diabetes. The percentage of patients exhibiting arteriosclerosis whose diabetes was of less than two years' duration was practically the same as those whose diabetes was from six to ten years' duration, as shown in the accompanying chart. This finding is in general agreement with Leutengegger's⁴ work and suggests that arteriosclerosis is more closely correlated with age than with the duration of diabetes.

TABLE 1—Causes of Death in Diabetes Mellitus with Average Age at Death

The prevalence of arteriosclerosis and its sequelae among diabetic patients is well known. The elaborate clinical studies of Joslin² indicate that arteriosclerosis appears prematurely among sufferers from this disease. Warren³ also states that pathologic evidence of arteriosclerosis was present in all cases of his series in which diabetes had been present for five years. However, he admits that his series is not typical of insulin-treated

cases. One could scarcely expect two series of cases to be completely comparable when one is selected from a pathologic and another from a clinical point of view. Pathologic criteria are certainly more exacting than either roentgen or clinical criteria. Clinical series would probably not reveal so much arteriosclerosis as would appear in pathologic series. Early sclerotic change of the arteries, particularly of the aorta, would naturally be missed by clinical examination but would appear in any series of pathologic studies. However, the relatively low incidence of arteriosclerosis in our series and in Leutenegger's⁴ series before the fifth decade, even in cases of long duration, may indicate a new phase in the history of diabetic management. Adequate insulin therapy may be changing the general picture. Also, we even dare to hope that more adequate nutrition, made possible by insulin, will arrest in the early stages the arteriosclerotic changes of the young diabetic individual.

NATURE OF THE DIET

There is considerable lack of understanding and some misunderstanding of the nature of higher carbohydrate diets. A higher carbohydrate diet does not mean an

Incidence of arteriosclerosis in 1005 cases of diabetes mellitus

unlimited or "free choice" diet such as Stolte⁶ has recently advocated. Table 3 shows the average type of diet that has been used during the period covered by this study in each type of diabetes. In each group the number of grams of carbohydrate has averaged slightly more than twice that of fat used. The tendency during the last few years has been to use from 3 to 4 Gm of carbohydrate per gram of fat without any change in the calory-to-kilogram ratio. The adults have received 30 or less calories per kilogram except when such complications as extreme malnutrition, tuberculosis or hyperthyroidism have been present. With children, we have been more liberal. The average diet served to all patients in the metabolic division of the Santa Barbara Cottage Hospital in 1926 was carbohydrate 206, protein 79, and fat 99, totaling 2,031 calories; in 1931 it was carbohydrate 184, protein 66, and fat 82, totaling 1,738 calories. We do not believe that this represents the degree of overfeeding that our critics have assumed.

In the preparation of the diets, all staple foods except cane sugar, honey, and foods sweetened with any of these are employed. Aside from this restriction, the

patient may select what particular foods he likes within the limitations imposed by the diet formula. In the institution, all diets are weighed, and the patients are encouraged to continue this practice at home. Fruits, vegetables, milk, eggs, meat, bacon, bread, cereals,

TABLE 3—Average Diet and Insulin Requirement

Diabetic Type	Age	Weight Kg	Diet					Insulin Units	Per Cent Discontinued Insulin
			Carbohydrate	Protein	Fat	Calories	Cal/Kg		
Juvenile	14	41.5	228	80	104	2,163	51	83	0.1
Adult (with insulin)	53	63	201	71	91	1,919	31.8	45	10.6
Adult (without insulin)	63	75	178	65	71	1,511	23.8	0	

butter, cream and salad dressings constitute the diet. The variety of foods offered adds attractiveness to the meals and helps to reduce to a minimum the feeling of "being on a diet." Adequate amounts and variety of minerals and vitamins are provided for on each diet. In short each diet is as nearly adequate nutritionally as it can be made under the circumstances.

Reluctance to accept the higher carbohydrate principle in planning diabetic diets has frequently rested on a fear lest these diets might require impossible amounts of insulin daily. Unfortunately, the early reports from this clinic dealt with severe and complicated cases principally¹ when larger doses of insulin were necessary. From table 3 it may be seen that our average child received 63 units of insulin daily and our average adult who took insulin, 45 units. All patients who used insulin for only a few days were excluded from this table. Only one of our children has been able to discontinue insulin entirely. To date, about 10 per cent of the adults who have taken insulin regularly have been able to discontinue its use. All save a very few of these patients live at a considerable distance from the clinic, so that the factor of personal supervision does not figure in our statistics as largely as it does in those from clinics that have a large local clientele. The non-insulin group represented naturally an older and more obese group in whom the disease would naturally tend to be milder.

END-RESULTS

We believe that the seven-year period covered by this study is a sufficient length of time in which to evaluate

TABLE 4—Seventy Cases of Diabetes Mellitus Treated with Higher Carbohydrate Diets Continuously for Seven Years

	Controlled	Partially Controlled	Uncontrolled
Number of cases	21	44	5
Average age (now)	53	46	32

adequately the usefulness of the higher carbohydrate diets. All patients included in this study received such diets throughout their period of treatment. Seventy were under continuous observation for the entire seven years, 16 for six years, 43 for five years, 57 for four years, 97 for three years, 115 for two years, 177 for one year, and 430 for less than one year. No case was included which did not receive treatment for at least one week.

⁶ Stolte, K. Freie Diät beim Diabetes. Med. Klin. 27: 831 (June 5) 1931.

Questions that have arisen during the course of this study are

1 Can diabetic patients partake of liberal diets without detriment to their metabolism or without excessive amounts of insulin?

2 Have these diets influenced the complications of diabetes?

3 Have they facilitated normal development of the children?

4 What is the patient's reaction to such diets?

5 Has demonstrable improvement in the patient's sugar tolerance accrued from this method of treatment?

In order to gain information regarding the end-results of this type of treatment, we have studied the records of those patients known to have used this type of diet exclusively for seven years. All these patients were communicated with recently in order to learn their present status. Table 4 shows the proportion of the cases which we consider to be satisfactorily or partially controlled and those uncontrolled. By satisfactory control we mean persistent maintenance of both a normal blood sugar level and sugar-free urine specimens. By partial control we mean occasional glycosuria or hyperglycemia. Uncontrolled implies persistent glycosuria and hyperglycemia. It is apparent from table 4 that the majority of these cases are, according to our arbitrary standard, only partially controlled. Several factors are involved here, among which are the distaste with which diabetic patients of long standing regard the continuance of weighing their diets while taking insulin, and the well known difficulty of persuading children and young adolescents of the advisability of making themselves conspicuously different from their associates as regards eating, in the interests of their health. Although the majority of the cases fall within our classification of partially controlled, it does not follow that for them the higher carbohydrate diet has been a failure. Physical vigor, mental alertness and social usefulness do not always register on metabolic progress records. Failure to show adequate laboratory control may also mean failure to apply in daily life principles learned in the diabetic classroom. The enthusiasm that the patients feel about our diet method is both gratifying and flattering. The feeling of robust health reported by the patients would in itself recommend this method. However, in order to be as objective as possible, we have confined ourselves solely to recorded laboratory data.

Our records are sufficiently complete on seventy of the original patients who received the higher carbohydrate diet in 1925 to justify critical analysis. All these patients have used the higher carbohydrate diet exclusively for seven years. A record of the age, weight, diet and insulin dose of each of these patients when they first became stabilized on the higher carbohydrate diet (first column) and the corresponding data when last examined (second column) are given in table 5.⁷ That an improvement in tolerance as measured by a lower insulin dosage, an increased diet, or both, has been frequent among these patients is apparent from a comparison of these two columns. In forty cases (57.1 per cent) there has been a reduction in the insulin dose either on the same diet or on one of greater caloric value. One patient has been able to increase his diet on the same insulin dosage, and another, who did not receive insulin, has been able to increase his diet without insulin. In ten cases (14.3 per cent) the insulin dosage today is higher than it was at the beginning of

the period of treatment, but the diets are also greater. Two patients (2.8 per cent) have had to increase their insulin dosage, either on the same diet which they took in 1925 or on one of lower caloric value. Fourteen cases (20 per cent) today require less insulin than they did five years or more ago, but at the same time the daily caloric intake is lower. The reductions in diet and in insulin dosage are not parallel in all cases. One patient now receives a lower diet with the same insulin dosage, while another, a noninsulin patient, shows a reduction in the diet. The lowering of the caloric intake in many of these cases does not mean loss of tolerance but merely indicates the general trend of management in recent years toward lower caloric diets, as may also be seen from the shift in our average diet of 2,031 calories in 1925 to 1,738 calories in 1931. Finally, in forty-two cases (60 per cent) there has been demonstrable evidence of improved tolerance during the period of time covered by this study.

Nine of the group who have used the higher carbohydrate diet continuously for seven years are children. Separate data of their status are presented in table 6. Only one of these nine children has lived up to our criteria for adequate control, hence most of them appear in table 4 among the partially controlled and

TABLE 6—Children Treated with Higher Carbohydrate Diets Continuously for Seven Years

9	22	69.0	?	*	212	100

* General unweighed diet

uncontrolled cases. The fasting blood sugar level of the juvenile cases has been uniformly high except when a nocturnal dose of insulin has been taken. In many cases we have intentionally allowed children to pass some sugar in the urine in order to prevent hypoglycemic shock while at school. Our margin is usually less than 10 Gm in the twenty-four hour specimen. Of the nine children, two have been admitted in coma, one twice and the other once. While some reduction in insulin dosage has been the rule, the amount of reduction is probably not of the magnitude indicated in the chart. Readmissions would naturally follow some break in the diet or some acute infection, with subsequent loss of tolerance.

It has been a real pleasure to note that the skeletal development of our children has not been appreciably retarded. Gray and Geyman⁷ failed to note the retarding effect of diabetes on osseous development, described by Joslin and his co-workers.² Priesel and Wagner⁸ also found normal development among their children. We are not prepared to claim that this improvement in osseous development is an exclusive virtue of the higher carbohydrate method, it is probably as much a result of feeding diets of greater caloric value. We suspect that when diets adequate in all nutritional requirements and insulin in appropriate amounts are employed, the

⁷ Gray and Geyman. Unpublished data.

⁸ Priesel, Richard and Wagner, Richard. *Körperbau, Wachstum, und Entwicklung diabetischer Kinder*. Ztschr. f. Kinderh. 41:267 1926.

development of children will progress at a normal pace. One of the triumphs of insulin is that it makes nutritionally adequate diets possible.

In order to illustrate briefly the results obtained, we wish to present synopses of the records of a few of the cases listed in table 5. These four cases were once treated in the Santa Barbara Cottage Hospital with a high fat, low carbohydrate diet, and some comparison between the low carbohydrate period and the high carbohydrate period in the same person is possible.

CASE 1—C. C., a man, aged 63, with no familial incidence, had had diabetes since he was 49 (1918). Neuritis was the only complication. The patient's previous diseases had been tonsillitis, sinusitis and sunstroke.

In April, 1924, the patient weighed 69.7 Kg, and on a diet consisting of carbohydrate 91, protein 79 and fat 193, totaling 2,417 calories, the urine was sugar free with 120 units of insulin daily. He was then changed to a high carbohydrate ratio, and eight years later, in 1932, he weighed 66.8 Kg and showed no urine sugar on a diet containing carbohydrate 224, protein 84 and fat 121, totaling 2,401 calories, with 60 units of insulin daily.

In this particular case the carbohydrate content of the diet was more than doubled, yet the insulin dosage was cut in half.

CASE 2—B. H., a man, aged 27, no familial incidence, had had diabetes since he was 17 (1922). There were no complications, and there had been no previous diseases.

In June, 1923, the patient weighed 57.5 Kg and on a diet consisting of carbohydrate 77, protein 65 and fat 182, totaling 2,206 calories, the urine was sugar free with 171 units of insulin daily. Nine years later, on the high carbohydrate diet, the weight was 62.2 Kg and on a diet of carbohydrate 199, protein 98 and fat 107, totaling 2,151 calories the urine was sugar free with 30 units of insulin daily.

In this instance, on a diet of about the same caloric value the carbohydrate content was more than doubled, yet the insulin requirement was materially reduced.

CASE 3—Miss M. F., aged 38, had had diabetes since she was 30 (1922). There were no complications. There was a previous history of lipoma. One brother had diabetes.

In 1923, the patient weighed 52 Kg and on a diet consisting of carbohydrate 93, protein 80 and fat 219, totaling 2,663 calories, the urine was sugar free with 30 units of insulin daily. Three years later, in 1926, the caloric value of the diet had been reduced to 1,884 with carbohydrate 232, the urine contained 15 Gm of sugar with 70 units of insulin. In 1932 on approximately the same diet, the insulin requirement had fallen to 34 units.

CASE 4—Mrs. M. F., aged 69, had one sister who had died of diabetes. The patient had had diabetes since she was 59 (1923). There were no complications. There was a previous history of otitis media and sinusitis.

In January, 1925, the patient weighed 63 Kg, and on a diet of carbohydrate 93, protein 71 and fat 93, totaling 1,493 calories, the urine was sugar free without insulin. In 1925 the patient was sugar free on a high carbohydrate diet of carbohydrate 189, protein 78 and fat 94, totaling 1,914 calories, with 24 units of insulin daily. Seven years later the diet consisted of carbohydrate 178, protein 67, and fat 59, totaling 1,511 calories, and the patient, who now weighed but 1 Kg more, required 25 units of insulin daily.

COMMENT

In prescribing higher carbohydrate diets, no distinction has been made between the insulin and the non-insulin patients. Insulin has been prescribed only when the patient was unable to metabolize an adequate diet without persistent glycosuria or prolonged hyperglycemia. A preliminary period of undernutrition was practiced during the early part of the period covered by this study but has since been abandoned as unnecessarily

prolonging hospitalization. The diets prescribed have fallen into three general groups: (1) maintenance, (2) "weight-reducing" and (3) "weight-gaining." By a maintenance diet we mean one that will maintain body weight constant at a level about 10 per cent below the average allowed in actuarial tables for age, sex and height. For adults, we have found 30 calories per kilogram of body weight sufficient. Many patients even maintain their weight for long periods of time on less without apparent detriment. Our children have received from 45 to 80 calories per kilogram of body weight, depending on their age.

As the average diets listed in table 3 indicate, we have used diet formulas containing 2 Gm of carbohydrate to 1 Gm of fat during the major part of the past seven years. For the past two years we have experimented with formulas having a carbohydrate to fat ratio of 3:1 and 4:1. Patients with mild diabetes have done well on such formulas, patients with severe diabetes have not. Even when low caloric diets such as reported by Rabinowitch⁹ have been prescribed, 4:1 ratios have not in our experience proved satisfactory in severe cases. We have found high fasting blood sugar levels and disturbing hypoglycemic shock to be common. Since the appearance of the first report from this clinic, a number of American and foreign clinicians have reported their individual experiences with higher carbohydrate diets (Adlersberg and Porges,¹⁰ Geyelin,¹¹ Barach,¹² Richardson,¹³ Poulton,¹⁴ Short,¹⁵ Stolte,⁶ Rabinowitch,⁹ Don,¹⁶ Nixon,¹⁷ Himsworth,¹⁸ Bang¹⁹ and Thomas and Howard²⁰). The common denominator of all these reports is the increased "feeling of fitness," mental alertness and physical vigor. That such desirable subjective values can be purchased at a moderate cost in insulin, our own observations and those of other clinicians demonstrate. Kestermann,²¹ who has applied Stolte's "free choice diet" to adults, also reports an increased sense of strength and well being, together with improvement in the patient's tolerance. We approve in general of Kestermann's liberal use of carbohydrate in his diets (from 300 to 400 Gm). We have, however, been fortunate in the past few years in that only infrequently have we found it necessary to prescribe doses of insulin as large as he has.

A recent summary published by Adlersberg²² presents his experience with the higher carbohydrate diet method and his evidence that improvement in tolerance, as measured by a reduction in insulin dosage or an

increased diet, occurs when the fat content of the diabetic diet is reduced and the carbohydrate content is correspondingly increased. That such improvement in diabetic tolerance follows the prescription of a higher carbohydrate diet has been noted repeatedly by the authors mentioned. As yet, however, no satisfactory explanation of the mechanism by which this improvement occurs has been offered. Porges and Adlersberg¹⁰ originally attributed it to a change from a liver rich in fat and poor in glycogen to one low in fat and rich in glycogen. Needless to say, this explanation, although highly attractive and stimulating, is purely theoretical. In his last publication, Adlersberg himself attributes little to it. An alternative hypothesis is that the taking of increased carbohydrate stimulates the secretion of endogenous insulin. Some evidence for this has been advanced by Porges and Adlersberg,¹⁰ Sweeney,²³ ourselves²⁴ and others. If true, it might be possible, reasoning *a priori*, to stimulate the pancreas to the point of exhaustion. With this possibility in mind we have examined carefully the records of those cases in which the higher carbohydrate diet was known to have been followed for seven years. Among these patients, if in any, one might expect to find evidence of exhaustion. Most of the patients showed a gain in tolerance when this diet method was used. In the case of the children, this gain occurred in spite of gains in body weight up to 100 per cent of the original weight. Adlersberg has claimed that overfeeding *per se* is not detrimental to diabetic tolerance but that overfeeding with fat is. In test periods of a few months' duration he has caused patients to gain weight with a high caloric, high carbohydrate diet and still has reduced their insulin dosage. Table 5 presents evidence of essentially the same thing over a period of years. This seems to answer satisfactorily and affirmatively the question raised at the outset of this paper, that it is not only possible and practical but also advantageous to feed the diabetic patient a diet that approaches a normal carbohydrate-fat ratio.

Don¹⁶ has recently reported on a group of sixty-one cases observed for from two to six years on diets providing up to 190 Gm of carbohydrate. In seventeen of these cases the dosage of insulin could be reduced, in twenty it had to be increased, while in twenty-four it was stationary.

An objection has been raised that the beneficial effect of this diet method is not the relative increase in carbohydrate but the relative reduction in fat. The observations of Czoniczer and Kolta²⁵ are the only ones that have come to our attention in which this question has been studied with equicaloric diets of constant protein content. These investigators found that the patient's tolerance rose equally well when liberal amounts of carbohydrate were permitted, whether very low or only moderately low (100 Gm) amounts of fat were employed. From this, one might assume that the relative increase in carbohydrate is the responsible factor.

SUMMARY

One thousand and five cases of true diabetes mellitus were treated with the higher carbohydrate diet method between Jan 1, 1925, and Jan 1, 1932.

Arteriosclerosis has been the chief single cause of death. The incidence of arteriosclerosis seems to be more closely related to the age of the patient than to the duration of the diabetes.

An improvement in sugar tolerance, as measured by either an increased diet or a reduced insulin dosage, was found in forty-two of seventy cases in which this diet had been used for seven years continuously. All patients reported a sense of increased well being and physical fitness.

IMMEDIATE PNEUMOCOCCUS TYPING DIRECTLY FROM SPUTUM BY THE NEUFELD REACTION

ALBERT B. SABIN, M.D.

NEW YORK

In recent years, pneumococcus typing has come to be a frequently performed clinical laboratory procedure. The definite indications for serum therapy in certain cases of lobar pneumonia render the determination of the type of invading pneumococcus essential in every case. The need for a simple, practical, rapid and reliable method has been recognized for a long time. Many methods of pneumococcus typing have been devised, but the one most commonly and successfully used was that in which the peritoneal exudate, obtained from a mouse on an average of from eighteen to twenty-four hours after injection of the sputum, was tested for agglutination with the various typing serums. In 1929, a stained slide microscopic agglutination method¹ was devised which was relatively more simple and rapid, giving results about three to five hours after injection of the mouse. This method has since been widely and successfully used. My purpose in the present communication is to introduce a method that is simple and reliable, that dispenses with the use of mice, and by which a correct determination of type is possible within a few minutes after a suitable specimen of sputum has been obtained.

As far back as 1902, Neufeld² observed that when pneumococci are mixed with specific immune serum there occurs in addition to agglutination a "quellung" (swelling) of the peripheral zone of the organisms. In 1929, I¹ was unable to demonstrate any specific change either in the microscopic appearance or the state of aggregation of pneumococci by mixing immune serum directly with the sputum; this failure, it appears now, was due partly to the fact that fixed instead of fresh preparations were studied and partly to the type of serum that was used. In 1932, Armstrong³ and Logan and Smeall⁴ in England reported simultaneously that, when sputum is mixed with immune serum and examined in the fresh state, one can observe the specific "quellung," described by Neufeld, and that pneumo-

coccus typing could thus frequently be performed within a few minutes. Several competent bacteriologists in this country attempted to use their method, in which sputum and serum are mixed on a slide, covered with a cover slip and examined with the high power lens (Armstrong) or the oil-immersion lens (Logan and

wards of Bellevue Hospital. The sputum was obtained from the patient by me in each instance, and the typing was performed almost immediately thereafter. In view of the fact that from a therapeutic standpoint it was essential to know chiefly whether or not the cases were type I or type II pneumococcus pneumonias, and also because rabbit serums⁵ for these two types only were available at the time, these were the only ones for which the sputums were examined. The results were checked with those obtained by the mouse methods in the bacteriologic laboratory of Bellevue Hospital.

METHOD

Two small flecks of sputum are placed on a cover slip (about 22 by 50 mm) with a platinum loop, the diameter of which preferably does not exceed 2 mm. When the sputum is very tenacious, as it frequently is, it may be necessary to use another wire for getting the sputum off the loop. To each bit of sputum an equal quantity of the undiluted rabbit serum (type I serum to one, and type II serum to the other) and a loopful of standard alkaline methylene blue was added. A special deep, large, hollow-ground glass slide, big enough to cover both drops, was used; this special slide is convenient but not essential. The edges of the slide are smeared with petrolatum, it is placed over the cover slip, and the preparation is inverted. The examination is made with the oil-immersion lens and an artificial blue light. Although the reaction occurs almost immediately, it is best to delay the examination for about two minutes to allow for proper diffusion of the serum.

It is important to observe that ordinarily, in the hanging drop preparation, pneumococci in sputum show no capsules, occasionally a faint halo of light but without any definite outline may be seen about the organism.

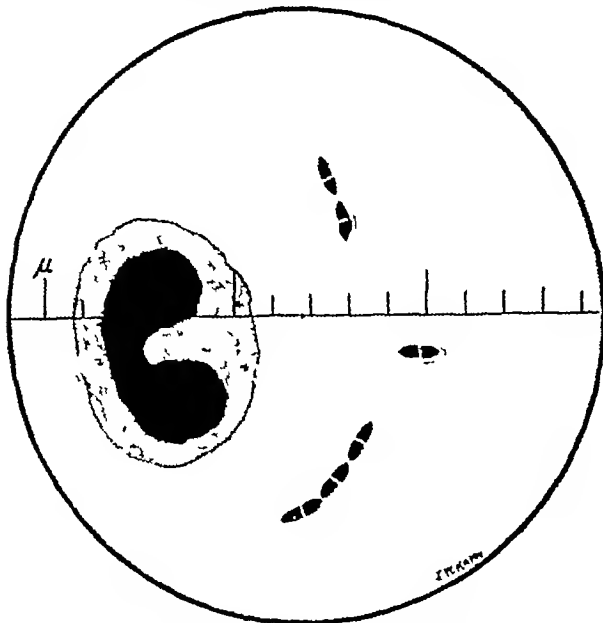

Fig 1—Type II pneumococcus in sputum mixed with type I anti serum (rabbit) no quellung

Smeall), but with little success. Some of the difficulties that were encountered were (a) the absence or small number of pneumococci in these preparations as well as the difficulty in finding them and (b) the rapid drying and frequent lack of specificity. Recently, Dr Kenneth Goodner of the Hospital of the Rockefeller Institute for Medical Research in New York observed the method as it is carried out in Professor Neufeld's laboratory of the Robert Koch Institute in Berlin, used it successfully himself in several cases and kindly demonstrated it to me. The technic differed from that of Armstrong and of Logan and Smeall in that the mixture was stained with methylene blue, to facilitate the detection of the micro-organisms, and was examined in a hanging drop instead of spread out in a cover slip preparation. After several trials in the laboratories of the Third (New York University) Medical Division of Bellevue Hospital had been successfully performed, this study was undertaken to investigate the factors that would make the procedure more uniformly reliable and practicable. Preliminary tests revealed that the following considerations were of great importance: (1) The horse antipneumococcus serums commonly used for typing were unsuitable for this method because they frequently gave nonspecific reactions, these nonspecific reactions could not be eliminated by dilution of the serum, since the "quellung" phenomenon occurs best with undiluted serum, (2) carefully prepared rabbit serum gives absolutely specific reactions, (3) whereas crystal violet or Wright's stain fails to stain the pneumococci in this preparation, alkaline methylene blue gives excellent results, and (4) the sputum should be typed not later than one to two hours after it is coughed up, because the pneumococci autolyze very rapidly.

With these considerations in mind, the method was applied to 100 cases of lobar pneumonia in the medical

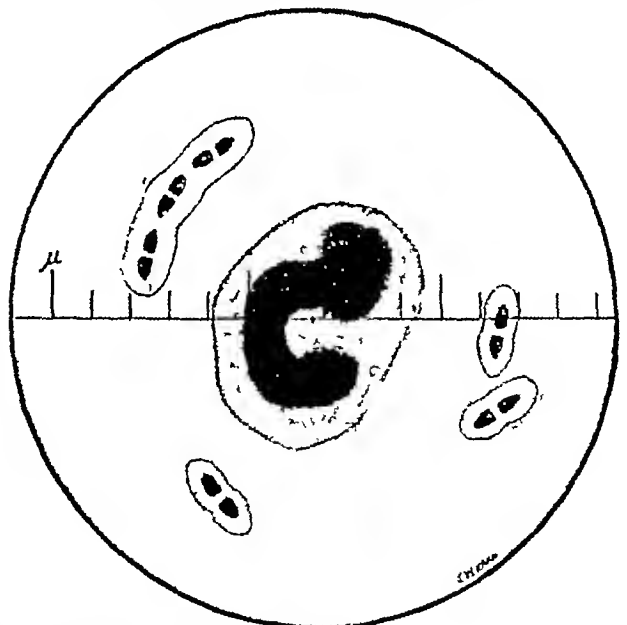

Fig 2—Type II pneumococcus in sputum mixed with type II anti serum (rabbit) 'quellung' reaction.

However, in the type-specific mixtures of sputum and serum one finds the pneumococci surrounded by peripheral zones of characteristic appearance and distinct

5 The author is indebted to Miss Georgia Cooper of the Research Laboratories of the New York City Department of Health for the rabbit serums. These serums had been kept without a preservative for over three years to prevent contamination, 0.5 per cent phenol was added to them during the course of this work.

outline This peripheral zone consists of a refractile substance which does not take the stain and which may be described as having a ground-glass appearance, the organism within it is stained blue The size of this zone of "quellung" varies in different sputums with organisms of the same type, generally, type II pneumococci presented the larger zone It is important to stress, however, that it is not so much the size of the zone as its characteristic appearance which determines a positive reaction It is also necessary to state that this reaction does not depend on agglutination of the pneumococci, although it occasionally occurs in the sputum, but on the appearance of the individual organisms, furthermore, this appearance is so characteristic that the finding of even a single diplococcus which shows it is sufficient to diagnose the type, as shown in the accompanying illustrations

RESULTS

Of the 100 patients who were typed by this procedure, 31 had type I pneumococcus, 22 had type II, and 47 had neither type I nor type II in their sputums There was not a single case of lobar pneumonia in which type I or type II pneumococcus was found by the mouse-inoculation methods that was not also found to be of the same type by this method of direct examination of the sputum In two instances, however, a type I pneumococcus was found by this procedure when no type was obtained by the older methods This method appears to be so specific that, when definitely positive, the results obtained by it should receive the greatest consideration Of the forty-seven sputums that contained neither type I nor type II pneumococci by the direct method, five were found to have type V, four type III, three type XIV, two each types IV, VII, VIII and XIII, and the remainder were scattered among the other types and the unclassified group of pneumococci, when tested by the mouse-inoculation methods It speaks well for the specificity of the direct method that not a single cross reaction occurred with any of these types, particularly so in the case of type V, which was formerly known as type IIa of Avery and which is closely related to the type II pneumococcus It is important to note also that ten of the thirty-one type I sputums and six of the twenty-two type II sputums were not of the typical "rusty" or "prune juice" variety, typical reactions for type I and type II pneumococci were obtained in a few almost purely salivary specimens The sputums of six patients who came to the hospital within from twenty-four to thirty hours after the onset of type I pneumococcus pneumonia presented in each instance sufficient pneumococci to permit an immediate determination of type, it is perhaps interesting to note that serum therapy was spectacularly effective in each of these patients

SPUTUM OF PATIENTS SUCCESSFULLY TREATED WITH SERUM

Shortly before, at or shortly after the time of crisis in many of the patients successfully treated with serum (only cases of type I and type II pneumococcus pneumonia, in all of which serum was given were observed), either the sputum on direct examination by this method was found to contain no pneumococci or else lancet-shaped diplococci were seen which did not give the "quellung" reaction In tests on pneumococci broth cultures it was observed that the organisms, shortly before undergoing autolysis, also failed to give

the "quellung" reaction Whether the lancet-shaped diplococci in the sputums already referred to were in that state or whether they represented different types of organisms cannot be stated It is necessary to point out, however, that persons desiring to familiarize themselves with this method had best not use such specimens of sputum

THE NATURE AND BIOLOGIC SIGNIFICANCE OF THE "QUELLUNG" PHENOMENON

In the early work on the "quellung" or swelling of the peripheral portion (capsule?) of pneumococci, Neufeld observed that the phenomenon required neither complement nor living organisms and that it did not lead to bacteriolysis It has been generally assumed, therefore, that the "quellung" represented an antigen-antibody reaction on the periphery of the organism of the same nature as that which precedes agglutination However, in this study certain important differences were found to exist Thus, a serum which could agglutinate in a dilution of at least 1:200 produced the "quellung" phenomenon irregularly in a dilution of 1:5 and not at all in a dilution of 1:10, even when normal or heterologous immune serum was used as a diluent, furthermore, an undiluted serum produced agglutination on a species-specific basis without any associated "quellung" of the pneumococci On the other hand, an undiluted serum failed to agglutinate because of a "zone phenomenon" but gave the "quellung" reaction nevertheless Pneumococci agglutinated by a dilute serum exhibited the "quellung" phenomenon on the addition of the undiluted homologous rabbit serum but not on the addition of the heterologous serum Larger "quellung" zones were observed with pneumococci in sputum than with those in the peritoneal exudate of a mouse, the latter, in turn, showed larger zones than the organisms in a broth culture The "quellung" of pneumococci in broth cultures was greatest early in their growth, diminished as the period of incubation increased, and shortly before they underwent autolysis (usually on the third or fourth day of incubation) showed no "quellung" at all When autolysis was prevented by heating the culture or exudate at 60°C for forty-five minutes, the organisms retained their "quellung" capacity for a long time A consideration of these various factors suggests that the "quellung" phenomenon involves something more than a mere combination of antibody with the organism In a recent publication, Ettinger-Tulczynska⁶ maintains that the "quellung" phenomenon represents a visualization of the natural capsule as a result of the precipitate that forms on it following the union of the capsular substance with the specific antibody, she was able to simulate this phenomenon, nonspecifically, by the addition of various precipitating salts to pneumococci Whereas this explanation appears plausible, it does not account for the fact that dilutions of serum which are capable of precipitating the so-called capsular substance are incapable of producing the "quellung" phenomenon

SUMMARY

The type of invading pneumococcus in lobar pneumonia can be determined directly from the sputum within a few minutes by a method that makes use of Neufeld's "quellung" phenomenon

THE TREATMENT OF POLIOMYELITIS

PREVENTION OF DEFORMITY AND PROTECTION
OF MUSCLESJOHN RUHRAH, M.D.
BALTIMORE

Jacob Heine, in 1840, in outlining the treatment of the deformities caused by poliomyelitis, recommended braces and the training of muscles. In his second edition, in 1860, he touched on the prevention of deformity. This, the paramount importance of rest, the protection of muscles from stretching and from the disastrous effects of fatigue, was fully discussed as to both principle and detail by Charles Fayette Taylor, in 1867. Hugh Owen Thomas, Sir Robert Jones, C. L. Lowman, Jean Macnamara and others have stressed these points, but deformities still occur and muscles continue to be damaged because this exact knowledge is not generally applied. Lovett, who was a great exponent of exercise, came to the conclusion that rest was the most important factor in treatment. One might say that the muscle paralyzed by poliomyelitis should be treated with the same care as a fracture as long as there is hope of improvement, together with the suggestions to be given.

It must be remembered that, while the primary lesion is in the nerve cells, secondary changes occur in the muscle fibers, and if these are stretched the fibers will be badly damaged, so much so that the muscle which would function eventually may be permanently paralyzed. This was well known in the 1860's but has largely been lost sight of. To give nature a chance to repair the damage and to prevent further injury, the muscles must be kept at rest in a position that will insure the greatest amount of recovery, which is when the attachments are brought as close together as possible, points brought out by Taylor in 1867. These two things are the basis of all rational therapy. Everything else may be looked on as secondary.

It must be borne in mind that the tendency in poliomyelitis is toward recovery and that, while there will be some residual paralysis in a proportion of cases, many muscles are needlessly sacrificed through neglect or improper treatment.

The principles of the management of the disease as I, a victim of it, see them, apart from any specific treatment with serum, may be stated as follows:

1 Deformity may be prevented. A start should be made as soon as possible. The patient is placed on a firm mattress with boards set transversely under it if necessary. Pillows should not be used under the legs. The patient should be kept recumbent in a suitable splint which will help relieve the acute pain so often present at the onset. The patient will welcome the relief and so become accustomed to the restraint. If not started at the onset, it should be done as soon as possible.

The nature of the splint, of course, will depend on the location and extent of the paralysis, but the main point to be remembered is that man is an erect animal and that the two muscle groups especially developed to enable him to stand erect, so differentiating him from the ordinary quadruped animals, are the glutei and the quadriceps. These muscles should therefore always receive especial attention, and they will be conserved best by keeping the patient, while recumbent, in the position he would be in if standing. As Taylor puts it,

If the patient has been carefully attended, so that no damage is done by faulty positions while in a state of muscular atony, there will be no difference in the rate of recovery, nor will there be shortening or lengthening of the different muscles, and the patient can begin to stand and walk at a much earlier stage, and with much less strength, than when a small amount of shortening has been allowed to take place. The reason for this is that the least contraction of the flexor muscles will at once throw the patient out of his natural position, and the weight of the body must be held entirely by the force of the muscles instead of resting on the bony framework, with only sufficient muscular aid to keep it erect.

A modified double Thomas frame splint made to extend from head to foot can be used to maintain the body in line so that eventually, when the splint is discarded, the patient will be able to stand erect, assuming that he will have recovered sufficient power to do so. Macnamara¹ gives the details of such a frame splint, which includes thoracic and pelvic bands, a corset to support the abdominal muscles, and adjustable arm and foot pieces. In place of this, other devices of plaster or metal may be used as well as sand-bags for adults. All splints must be used with thought.

Great care should be exercised in preventing slight deformities from the irregular return of muscle power. The line between the anterior superior iliac spines should be at right angles to the line passing straight down through the center of the body. The weaker muscles should be relaxed by position to prevent stretching by stronger opposing ones, for example, the quadriceps by keeping the leg extended but not so as to cause hyperextension. It should be remembered that the causes for subsequent deformity develop early, and prevention should start at once. The trunk muscle abdominals and the hip extensors are usually neglected with appalling results. The glutei and the quadriceps should always be kept in mind.

2 Relaxation and rest are the most important factors in treatment. Fatigue, both general and local, must be guarded against. The patient's sensations are not a good guide. An amount of fatigue, dangerous alike to nerve centers and muscles, may not be noted until it is too late. Fatigue from exercise must be carefully watched for, as noted under muscle training.

3 The muscles must be protected. Overstretching a normal muscle will paralyze it temporarily and overstretching a paralyzed muscle may damage it permanently. The stretching may be due to the force of gravity, as in the examples of the deltoid, the quadriceps and the tibialis anticus. This stretching may be due also to the pull of stronger antagonistic muscles. Both of these forms may be prevented by the use of properly adjusted splints changed from time to time to suit existing conditions. Much injury may be done by allowing the patient's arms or legs to dangle in handling him. A muscle will recover its power more quickly and completely in complete relaxation than in any other position. A relatively weak muscle may in this manner become stronger than the one which originally opposed it, and a change in splints must be made accordingly.

4 Contractures must be prevented. Contractures are due to shortening in unopposed and relaxed muscles, tendons and fascia. Proper splinting and the daily bath at which time proper passive exercises may be undertaken, will prevent them.

Muscles should never be allowed to stretch while the child is being moved or while treatment is being given. This should be limited at first to daily warm baths,

when tenderness and pain pass, a program of very gentle massage, and a very little passive motion, to be replaced by voluntary exercise under supervision as outlined, may be undertaken

Muscle training can be carried out on a table on a Mackenzie board, that is, the legs or arms may be exercised on a suitably sized smooth board well powdered, placed on pillows or under water. The exercises are done first on a flat surface with gravity eliminated, later the board may be inclined, still later, gravity may be allowed to a greater extent. In the water the physical therapist, if necessary, supports the limb that is being exercised.

The exercise is started with very little motion, one or two movements, and gradually increased. If the muscle fails to make the movement easily, a sign of fatigue, the exercise should be stopped and the rest period awaited.

5 At first the more important muscles should be favored until their recovery is assured. These are the deltoids, the extensors of the wrist, the opponens of the thumb, the glutei, the quadriceps, the calf muscles, the invertors of the foot and the abdominal muscles.

6 Muscles may be reeducated and strengthened by suitable exercise. In the early stages a daily warm saline bath will be all that is needed. Later, when the pain and tenderness have passed off, a small amount of daily exercise may be given. In America, this treatment has been overdone and the measures to insure the fundamental protection have been overlooked.

If a movement cannot be made voluntarily, it should be made passively and the patient encouraged to will it. The value of volition in muscle training was stressed by John Hunter in the eighteenth century and by Roth in 1869, among others. A weak muscle may be assisted. A muscle should never be permitted to become fatigued. During the exercise it should be seen that the other muscles are protected.

The advantage of under-water treatment is that gravity, i. e., the weight of the limb, is largely eliminated, the patient can make volitional movements impossible in the air. May complete motions, learns coordination, and gains in confidence and morale, a factor that only one who has been through it can appreciate. The arc of motion should in all exercises be completed either with or without assistance. The use of "trick" movements or "cheating," in which the patient produces the movement by using another group of muscles than the one ordinarily used, should not be permitted.

7 The exercise given must always be well within the capacity of the muscles. The exercise must not be by rule of thumb but should be regulated each day, for each patient and for each muscle group.

8 The treatment should be individual and modified from time to time to suit conditions as they arise.

9 The muscles should be protected and trained as long as there is any improvement.

10 When muscles of the trunk and legs are involved, weight bearing should not be allowed while improvement is going on if the aim is to achieve all the recovery possible, but only after it has come to a standstill.

The time to let the patient up is always a question. Macnamara continues a regimen of accurate splinting in the recumbent position as long as there are signs of improvement. After a year, if there is no evidence of further improvement, suitable braces may be supplied and the training directed to securing the best possible result as to function. Prolonged treatment often avoids the use of braces later.

11 Warmth is useful. The muscle should be warmed before exercise. Dry heat may be applied in tents or boxes fitted with carbon bulbs, improved appliances or other means. Fresh air, sunlight and ultraviolet rays in properly graduated doses are of value in improving the general condition. Massage, if used, should be gentle and, if there is any tenderness, avoided.

Warm baths are most useful and are gratifying to the patient. A warm bath, preferably of salt water, should be given daily. Small children may be bathed in a tub, the muscles being supported during the bath and care being taken to avoid the dangling of limbs in handling the child. Macnamara² advises bathing adults in bed by placing a rubber sheet under them and pinning it with clothes-pins to boards lugged to the sides, and foot of the bed and over pillows to the back. The water is drained out by pulling a part of the sheet through a hole in one of the boards. When not in use, the boards are dropped to the side of the bed. Any good mechanic can attach gadgets to the bed to hold strong wires to be used for this purpose.

12 The morale of the patient should be kept up. The child should not be humored or spoiled, self pity will down the strongest. Those around poliomyelitis patients should remember the saying of Dr. John Brown about pity ceasing as an emotion and becoming a motive. Suitable amusements for young and old, education by mail or by teachers, games, radio, music and visitors help to pass the hours. An unoccupied person cannot be expected to be happy. Too often patients are allowed to stew in their own mental juices to their great detriment. Education, diversion or visiting should not be overdone. Proper mental rest is as essential as physical rest but, as the Scotch saying goes, "It is possible to get too much pork for a shilling."

SUMMARY

In managing patients paralyzed by poliomyelitis, one should bear in mind that deformity is preventable, rest is essential as long as there is hope of improvement in muscle power, the muscles must be protected from damage by stretching and fatigue, a muscle placed at rest in a position of relaxation, i. e., with the attachments brought as close together as possible, will recover sooner and more completely, the patient should be kept recumbent (in proper line, i. e., in the same alignment as if standing erect), weight-bearing is not to be allowed while recovery is occurring if the best results are to be obtained, and much of the crippling resulting at present may be avoided.

The Gold Content of Sea Water—When the World War was over and the victors imposed upon Germany the task of finding enormous sums for "reparations," Fritz Haber proposed to himself the most interesting scheme of extracting gold from the inexhaustible reservoir of the oceans. Previous determinations by other investigators had placed the gold content of sea water at five to ten milligrams of gold per metric ton (one thousand kilograms) of water. The gold ores of South Africa contain about one thousand times more gold per ton than does sea water, but the greater ease of working water, as compared with rigid rock, made the task seem very promising. The plan itself did not succeed and could not succeed. Instead of the assumed gold content of five to ten milligrams per ton, Haber's numerous experiments showed only about one thousandth as much. But they accomplish a great advance in the analytical methods for separating out minute amounts of material—Hahn, Otto. From the Ponderable to the Imponderable, *Science* 77: 398 (April 28) 1933.

APOMORPHINE AS AN ANTIDOTE TO
STRYCHNINE POISONINGDAVID GOLD, BA
AND
HARRY GOLD, MD
NEW YORK

In the course of another study the observation was made that a combination of morphine and apomorphine in very small doses, which by themselves produced no appreciable depression, gave rise to an unusual degree of motor fatigue. Experiments were then planned to determine whether this action might prove useful in antagonizing the actions of strychnine, in view of the recent report by Haggard and Greenberg¹ that in dogs and rats convulsions are diminished and recovery

dogs. Unless it can be shown that apomorphine is fairly consistently effective against strychnine poisoning it might prove disastrous to place reliance on a dose of apomorphine which is usually much more readily available in practice than the effective methods for the treatment of strychnine poisoning which have come into vogue during the past few years.

Experiments were designed to ascertain (1) whether apomorphine would diminish the reflex excitability caused by nonfatal doses of strychnine, and (2) whether apomorphine would prevent paralysis of respiration after doses of strychnine that are fatal for normal animals. In some cases in which it was possible, the same animal was employed for more than one experiment.

Sixteen experiments were carried out on eleven dogs. Strychnine sulphate and apomorphine hydro-

* Apomorphine was given in two doses in these cases. In all others apomorphine was given in one dose.

† In these cases the strychnine was given before the apomorphine. In all others the apomorphine was given first.

occurs after the administration of more than the single fatal dose of strychnine when the animals are treated with apomorphine, and in view of Dr Martin's report, quoted by these authors, indicating that similar results can be obtained in man.

In preliminary experiments the combination of morphine and apomorphine in very small doses proved entirely ineffective against strychnine poisoning, and the plan was not pursued further, but in one experiment a very large dose of apomorphine also proved ineffective. This suggested the need of confirming the report of Haggard and Greenberg, especially because the conclusion regarding the effectiveness of apomorphine appears to have been based on the recovery of only two

chloride were used in 1 per cent solutions. Both drugs were injected intraperitoneally. The doses in all cases were calculated in terms of milligrams of the drug per kilogram of body weight. The results in some detail have been summarized in table 1.

Haggard and Greenberg accepted 0.7 mg of strychnine (sulphate?) per kilogram as the surely fatal dose by intraperitoneal injection in the dog. They injected 1 grain (64.8 mg) of apomorphine, which we assumed to be the total dose for their dogs, but since they did not state the weight of their animals, we assumed that dose to represent about 5 to 10 mg of the drug per kilogram of body weight. They gave the strychnine first and the apomorphine when hyperexcitability or convulsions appeared. In the two dogs in which we proceeded in this way, convulsions continued uninfluenced by the apomorphine until death in forty and

seventeen minutes respectively after the strychnine (dogs 3 and 6b). In the first of these the fatal dose of strychnine was only 0.53 mg per kilogram.

In the remaining experiments the apomorphine was given in one dose prior to the strychnine or in two doses, 5 mg at varying intervals before the strychnine and 5 mg after symptoms of strychnine poisoning appeared. The apomorphine caused vomiting in all instances except the two in which strychnine convulsions were produced before the apomorphine was given. It also produced periods of marked motor unrest during which the animal paced about the room continuously, alternating with periods of motor weakness during which the animal refused to stand and lay with the legs sprawled out. In some cases this modified somewhat the reaction during strychnine poisoning, namely, the animal made more frequent attempts to rise, precipitating convulsions, and exaggerated motor depression occurred between the convulsions.

Table 2 shows the effect of 0.35 mg of strychnine sulphate in each of six dogs. The maximum effect of the same dose varied considerably in different animals, from slight hyperexcitability to convulsions, and complete recovery required from sixty-seven minutes to more than a hundred and sixty-nine minutes. In the one dog of this series (dog 4) that was treated with apomorphine the hyperexcitability continued uninfluenced, and recovery took place no sooner than in the untreated animals. The experiments of the next series confirm the observation of the absence of any antispasmodic effect of apomorphine.

Table 2 also shows the effects of a uniform dose of 0.7 mg of strychnine sulphate in dogs receiving apomorphine. This dose of strychnine caused typical convulsions in all these animals, and death in six of eight experiments in which apomorphine as well was administered. In one case (dog 8b) the animal

formly so, and that the animal which will at one time recover from such a dose may at another time succumb to it.

CONCLUSIONS

The results of these experiments lend no support to the statement by Haggard and Greenberg that apomorphine controls strychnine convulsions in dogs and permits recovery from approximately twice the lethal dose of strychnine. Our results in a larger series of experiments show, on the contrary, that there is no appreciable antagonism between apomorphine and strychnine in dogs, that the reflex hyperexcitability from nonfatal doses of strychnine is not diminished and that death from doses fatal to untreated animals is not prevented by the administration of apomorphine. Possible sources of error that may indicate an antagonism between the two drugs are pointed out, namely, considerable variation in the degree of hyperexcitability after similar doses of strychnine in different dogs, as well as differences in susceptibility of the same dog at different times.

PERNICIOUS ANEMIA AND TUBERCULOSIS IS THERE AN ANTAGONISM?

A REVIEW OF THE OCCURRENCE OF TUBERCULOSIS IN NINETY-THREE CASES OF PERNICIOUS ANEMIA AS FOUND IN 16,600 POSTMORTEM EXAMINATIONS WITH A REPORT OF TWO CLINICAL CASES

MOSES BARRON, M.D.
MINNEAPOLIS

Observers are almost unanimous that patients suffering from pernicious anemia remain practically free from active tuberculosis. In fact, so infrequent is the association of these two diseases that most of the textbooks on pathology and hematology as well as on clinical medicine do not even discuss it, and, in talking over this matter with clinicians as well as with pathologists of wide experience, I have been impressed with the fact that they have practically never encountered instances of such association. What is even more striking is the absence of material on this subject in the English literature and the scarcity of it also in the foreign literature. It is for this reason that I consider it a rare opportunity to have encountered two such cases, which I shall attempt to present, together with a review of what little is available in the literature.

REVIEW OF LITERATURE

Mathias¹ cites the pathologic statistics from Breslau in which not a single case of active tuberculosis was found in all the pernicious anemia cases. In his own carefully studied series of thirty-six cases of pernicious anemia there was not a single instance of active tuberculosis present. He considers this freedom from tuberculosis in pernicious anemia so striking that he asks for the experience of other observers in regard to this matter. He points out that this apparent antagonism is the more notable since, as Rokitsky has shown, cases of chronic malnutrition—diabetes, malignant growths and cachectic states—usually predispose to the activation of dormant tuberculosis. Mathias suggests

				11	5	Death	

* Received only 0.53 mg of strychnine sulphate

recovered from 0.7 mg of strychnine sulphate when given 10 mg of apomorphine, five days later a similar dose of strychnine without the apomorphine was fatal (dog 8c). It indicated the possibility of a protective action of the apomorphine. This interpretation was vitiated, however, by the observation in another animal in which recovery from 0.7 mg of strychnine sulphate occurred when 5 mg of apomorphine was given, but a similar dose of strychnine given six days later was fatal, although even a large dose of apomorphine was administered, namely, 5 mg before the strychnine and 5 mg after strychnine convulsions appeared (dogs 10a and 10b). It is evident, therefore, that 0.7 mg of strychnine sulphate, while usually fatal, is not uni-

that perhaps the oxygen deficiency resulting from the anemia precludes tuberculous activity

Neuburger² hints at the possibility that the excessive erythrocytolysis might act as an inhibitory factor against tuberculosis but at the same time tries to point out the fallacy of such an assumption by citing the relative frequency of tuberculosis in congenital hemolytic jaundice, in which erythrocytolysis is even more pronounced. He reports a case of congenital hemolytic anemia in which the patient died of extensive tuberculosis. He believes that there is probably some constitutional factor which, while predisposing to the development of the anemia, at the same time produces a refractoriness to tuberculosis. This concept would place pernicious anemia as a distinct entity which already exists in the patient long before any clinical manifestations of the disease develop.

Berger³ similarly states that the debris of excessive erythrocytolysis cannot explain the rarity of the combination. He cites an interesting case of pernicious anemia developing six years after subtotal gastrectomy for carcinoma. There were characteristic exacerbations and remissions during a period of three years with the usual blood picture, neurologic changes and achylia. Under liver therapy and hydrochloric acid the anemia improved, but during one of these remissions the patient developed generalized milary tuberculosis and died.

Qvarnström⁴ is not entirely in accord with the preceding authors and concludes from his careful studies that there is neither a predisposition nor an antagonism between pernicious anemia and tuberculosis. He believes that each disease seems to run a course entirely independent of the other. He cites two cases in which the two diseases coexisted. In a series of 10,500 autopsies at Helsingfors, performed between 1886 and 1929, there were found 124 cases of pernicious anemia, of which 33 were associated with the fish tapeworm. In these 124 cases, 5 showed active tuberculosis and 7 showed healed lesions. He seems to find no difference between idiopathic pernicious anemia and the anemia of fish tapeworm in their relation to tuberculosis and therefore did not attempt to separate them.

Strandell⁵ made an intensive study of pernicious anemia in a series of 117 cases carefully followed during a period of many years. In this series he found four cases of active tuberculosis superimposed on pernicious anemia, but only one showed active pulmonary tuberculosis, the others being intestinal, peritoneal and generalized milary tuberculosis. He concludes that the association of the two diseases is very unusual.

From this brief review of the literature it is evident that the coexistence of the two diseases is exceedingly rare. Most of the authors sense an antagonism between the two diseases but have difficulty in explaining the basis for it. That the oxygen deficiency theory is untenable is proved by the fact that tuberculosis does not develop either in the period preceding the onset of severe anemia or during the long remissions, when the oxygen content in the blood is normal. Neither is there any good foundation for the assumption that the cellular debris resulting from excessive hemolysis prevents the growth and development of the tubercle bacillus, for, as previously mentioned, tuberculosis does

occur in congenital hemolytic jaundice. Qvarnström⁴ is the only one who believes that he found neither antagonism nor predisposition, but since his studies are from Finland, where infestation with the fish tapeworm is so very common, it is quite likely that the relative frequency of association of tuberculosis with anemia might be explained by the fact that many of these anemias may have been due to the fish tapeworm and were not true idiopathic anemias. He plainly states that he made no attempt to differentiate the two types. Schauman and Saltzman⁶ have found that the frequency of tuberculosis in the tapeworm anemias is fairly common but very rare in idiopathic pernicious anemia. They give a lengthy discussion on the relationship between pernicious anemia and tuberculosis and cite authorities⁷ who state that in all their experience they have never seen a combination of tuberculosis with the idiopathic variety.

REVIEW OF POSTMORTEM CASES

In order to determine the frequency of tuberculosis with pernicious anemia in a large series of cases, the postmortem records of more than 16,000 autopsies, performed from 1920 to 1932, inclusive, in the Department of Pathology at the University of Minnesota Medical School were examined. In this series, ninety-three cases of pernicious anemia were found. All of these were strikingly free from active tuberculosis. Ten of these cases showed chronic adhesive pleuritis, of which undoubtedly a high percentage was tuberculous, but the lesions were all healed. There were three cases of arrested or healed nonclinical pulmonary tuberculosis and one case of healed milary pulmonary tuberculosis. In the entire series of ninety-three cases there were present only two cases of active tuberculosis, and both of these were acute generalized milary tuberculosis, which was the direct cause of death in these patients. The absence of active chronic pulmonary tuberculosis is very striking. In a similar study on tuberculosis and cancer in a series of more than 11,000 autopsies, Carlson and Bell⁸ found that, although there is apparently no antagonism between cancer and tuberculosis, active tuberculosis is much less frequent in persons with cancer than in the general postmortem series. They also found that cancer is relatively less frequent in active tuberculosis. From a knowledge of the incidence of these two diseases in the different age periods, one would expect a lowering of the incidence in the combination since the peak of tuberculosis frequency is in the middle of the third decade, a period in which the carcinoma incidence is very low, since it is just beginning. From then on the carcinoma incidence increases until it reaches its peak about the sixth decade. Although tuberculosis seems less common in cancer patients, nevertheless a combination of the two is encountered not infrequently. This is quite in contrast to the incidence of tuberculosis in pernicious anemia, where one would expect more frequent coexistence, since the greatest incidence of pernicious anemia occurs earlier than that of cancer and therefore during a period when tuberculosis is still relatively frequent. Yet our entire series of ninety-three cases of pernicious anemia did not present a single case of chronic pulmonary

tuberculosis and only two cases of miliary tuberculosis. This result completely coincides with the reports in the literature in which occasional cases of acute miliary tuberculosis are reported but practically no cases of progressive pulmonary tuberculosis. It is obvious that cases of miliary tuberculosis present a type of acute infectious disease spread by the blood stream altogether different from chronic pulmonary tuberculosis. The factors of immunity and resistance are entirely different in the two diseases. It is therefore not unreasonable to conclude both from a review of the literature and from a study of a large series of postmortem cases that chronic progressive pulmonary tuberculosis is only on the rarest occasions associated with pernicious anemia.

REPORT OF CASES

CASE 1—B T, a man, aged 67, first seen May 17, 1927, complained of marked weakness, loss of appetite, nausea and gastric distress and a loss of 25 pounds (11 Kg). In September, 1924, his condition was definitely diagnosed as pernicious anemia. At that time he had a characteristic history, clinical and laboratory findings, including achylia gastrica, and a negative gastro-intestinal study. He had attacks of gastric distress and a marked glossitis, the heart and lungs were entirely normal. During three years observation his blood picture varied, the hemoglobin between 59 and 74 per cent, the red count between 1 900 000 and 3 300 000, the leukocyte count from 2 300 to 3 300, and the hemoglobin index above 1, generally around 14. The patient left for California, Nov 15 1926, and while there a pleural effusion developed which was diagnosed tuberculosis in March, 1927. When seen after his return in May, 1927, he was markedly underweight, his temperature was around 100 F, and his pulse, 110, he looked pale and was emaciated. The tongue was apparently normal and the chest showed poor expansion with dullness and numerous crepitant and subcrepitant rales over the right upper lobe, the liver was slightly enlarged, the spleen was not palpable and vibration sense was decreased in both legs. Roentgenograms of the chest showed extensive infiltration of the right upper lobe, some infiltration of the middle lobe and a slight infiltration of the left apex. Several sputum examinations showed numerous tubercle bacilli present. The diagnosis was active bilateral tuberculosis, with a small amount of fluid at the left base. A repeated gastric analysis showed an achylia present. The blood picture now showed 44 per cent hemoglobin, 1,700 000 red blood cells, hemoglobin index 13, leukocyte count 8 200 with a differential showing a few myeloblasts and myelocytes. June 2, the hemoglobin was 68 per cent, red count 3,300,000 and leukocytes 9 700, July 20, the hemoglobin was 46 per cent and leukocytes 26,500 of which 79 per cent were polymorphonuclears, 6 per cent lymphocytes, 9 per cent mononuclears and transitionals, 1 per cent eosinophils and 5 per cent myelocytes. The granulocytes showed a definite shift to the left. The patient was given several blood transfusions with some improvement of the blood but no change in his general condition. He had a progressively downhill course with an irregular temperature reaching 103.5 F. He became bedridden and markedly emaciated and died from a rapidly spreading tuberculosis of both lungs, September 22.

This case is unique in showing the development of a rapidly spreading pulmonary tuberculosis in a man suffering from pernicious anemia of at least four years' duration. The tuberculosis ran a course of about six months and finally caused the death of the patient. The blood picture seemed to improve at a time when the infection was active and spreading. The virus of the tuberculosis altered the blood picture in that the leukopenia changed to a normal leukocyte count and finally to a moderate leukocytosis (26,500). The polymorphonuclears showed a definite shift to the left and, toward the end, many metamyelocytes and myelocytes appeared. This condition was probably the result of a toxic stimulation on an embryonic type of bone marrow.

The hemoglobin index remained high throughout. This case as well as the succeeding one seemed to support the statement of Qvarnström that, when the two diseases do coexist, one does not seem to modify the course of the other.

CASE 2—Mrs G L, aged 68, admitted to the hospital, Oct 2, 1932, complained of weakness and tingling of the hands and feet and difficulty in walking. Four years previously a severe anemia developed, which proved refractory to treatment and which later continued with exacerbations and remissions. In 1931 her condition was diagnosed pernicious anemia, she was given desiccated hog stomach, with some improvement. Physical examination at the present admission showed a pale lemon yellow skin, appetite poor, hemoglobin 17 per cent, red count 1 300 000, leukocyte count 1,900. She was given a transfusion, following which the hemoglobin one week later was 34 per cent, red count 1 800 000, leukocyte count 3,800. The temperature ranged from 98 to 101 F. She then went home for a short period, at which time she developed pain in the right chest, a cough with expectoration, chilliness, tingling sensations occasionally of the hands and feet, and later a pleural effusion. She was readmitted with a hemoglobin of 58 per cent, red count 2,100 000, leukocytes 7,600 and hemoglobin index 14. The patient died suddenly, November 14. The autopsy showed a massive miliary tuberculosis of both lungs with abscesses at the base of the right lower lobe, chronic adhesive pleuritis, generalized miliary tuberculosis of the liver and spleen, tuberculosis of the peribronchial lymph nodes, and hemosiderosis of the liver. The diagnosis was pernicious anemia and miliary tuberculosis.

This case showed an extensive miliary tuberculosis which resulted in the death of the patient. The patient also had a history of pernicious anemia of about four years' duration. The blood picture showed a progressive improvement, while the tuberculosis was rapidly spreading and the case was on a downhill course. This case is very similar to the two cases reported by Qvarnström.

SUMMARY AND CONCLUSIONS

- 1 Chronic pulmonary tuberculosis in pernicious anemia is so rare that its incidence is practically negligible. The mechanism of this inhibition of tuberculosis is unknown, but it is probable that some constitutional factor which underlies the development of pernicious anemia proves unfavorable for the evolution of pulmonary tuberculosis.

- 2 Whenever the two diseases do coexist, each seems to pursue a course entirely uninfluenced by the course of the other.

- 3 In case 1, the infectious disease altered the leukocytic picture by producing a definite shift to the left and the appearance of numerous metamyelocytes and myelocytes.

- 4 Acute miliary tuberculosis is somewhat more common as a complication of pernicious anemia.

- 5 In a series of 93 cases of pernicious anemia found among 16,600 postmortem examinations, only 2 cases of active tuberculosis of clinical importance were found, and both of these were acute generalized miliary tuberculosis. Not a single case of clinical chronic pulmonary tuberculosis was encountered in the entire series.

- 6 Four cases of tuberculosis complicating pernicious anemia are here reported, two are from postmortem studies and two from personal observation. Of these, three were acute general miliary tuberculosis and only one was chronic pulmonary tuberculosis.

- 7 The freedom of pernicious anemia cases from tuberculosis cannot be explained by the fact that "a person usually has only one major disease."⁸ There must be an antagonism between them.

Clinical Notes, Suggestions and New Instruments

EPHEDRINE AND PICOOTOXIN USED SUCCESSFULLY IN AMYTAL POISONING

JOHN H. ARNETT M.D. PHILADELPHIA

A girl, aged 3½ years, at about 11 30 a. m., seemed excited and fretful, threw herself about and talked incessantly with a thick enunciation. She fell down again and again in attempting to walk. Her eyes wandered and were apparently unable to fix on any object. Soon she became drowsy and was unable to stand, owing apparently to weakness in the lower extremities.

At 11 50, an open box which had previously contained several (probably not more than four) 1½ grain (0.1 Gm.) tablets of amytal (isoamyllethylbarbituric acid) was found in the room in which she had been playing. The child was promptly given two teaspoonfuls of syrup of ipecac, which produced vomiting at 12 20 p. m., the vomitus being saved and later giving a positive reaction for the barbitol derivatives. I saw her at 1 20, at which time she showed flushing of the face and unconsciousness, vigorous shaking arousing her only partially. Gastric lavage was employed, followed by the administration through the tube of ½ grain (0.05 Gm.) of ephedrine sulphate and an unmeasured quantity of magnesium sulphate solution.¹ At 2 o'clock, ¼ grain (0.00065 Gm.) of picrotoxin was administered hypodermically.

The passage of the stomach tube and the administration of the hypodermic evoked crying and a slight struggle, but she lapsed into unconsciousness again immediately and could not be aroused by calling or shaking. Even when struggling the head hung limp, and the muscles of the neck and lower extremities appeared extremely weak. There was ptosis of the eyelids. At this time the systolic blood pressure was 90 mm. of mercury, and the pulse was 120. Respirations were not noticeably changed in rate or depth. At 2 30 she vomited, seemed much brighter, and was able to stand alone, leaning against the side of the bathtub. At 2 45 a soapsuds enema was given, resulting in a small stool. She was still drowsy, but could easily be aroused. At 3 45 a second dose of ¼ grain (0.00065 Gm.) of picrotoxin was administered hypodermically. She vomited twice more during the afternoon, but continued steadily to improve, and was able to come downstairs for dinner, though she fell asleep during the meal. On the following day she played about the house as usual and had two liquid stools. No untoward later results were noted.

The use of ephedrine in the treatment of poisoning with the barbitol derivatives was suggested by the work of Schmidt² and of Chen and Schmidt³ who found it to have an exceedingly powerful stimulating action on the respiratory center. It was found by Cameron and McCulloch⁴ to be of decided value in the treatment of nembutal (sodium-ethyl methyl butyl barbiturate) poisoning in animals.

Picrotoxin is a neutral principle derived from the fruit of *Anamirta paniculata* and has the empirical formula $C_{20}H_{14}O_{10}$. It was formerly used orally in the treatment of various conditions, including the night sweats of phthisis, in doses of from ½ to ½ grain (0.003 to 0.001 Gm.) for adults. It stimulates the medulla, and in large doses produces convulsions. Its action resembles somewhat that of strychnine, though it probably acts on a different part of the central nervous system.⁵ It has not been included in the United States Pharmacopeia, tenth decennial revision or in other pharmacopoeias except those of France and Mexico.⁶ Its use in acute poisoning with the barbitol derivatives has been studied in animals by Maloney,

Fitch and Tatum⁷ and by Maloney and Tatum⁸ who found that picrotoxin shortened the recovery period when sublethal doses of the barbitol derivatives were given to animals and effected a cure when lethal doses within certain limits had been given.

As far as I am aware, this is the first report of the use of either ephedrine or picrotoxin in a human case of poisoning by any of the barbitol derivatives. Since this type of poisoning is becoming increasingly more common, it is hoped that others using this form of treatment will report their results in order that the value of these drugs may be established or disproved.

SUMMARY

A girl, aged 3½ years, took a toxic dose of amytal the exact amount not being known. Emetics and gastric lavage were given. Ephedrine, ½ grain (0.05 Gm.), and magnesium sulphate were administered by stomach tube. Two doses of picrotoxin of ¼ grain (0.00065 Gm.) each, were given hypodermically. Improvement progressed with surprising rapidity, resulting in complete recovery.

THE USE OF AMIDOPYRINE IN A CASE OF DIABETES INSIPIDUS

• BERNARD S. KAHN M.D. NEW YORK

In July, 1932, Scherf¹ made a report on the use of amidopyrine in the treatment of diabetes insipidus. I had at that time a patient suffering from this disease whose only relief from the great frequency of urination was daily injection of a pituitary preparation. Numerous attempts to alleviate his symptoms by oral administration of large doses of desiccated pituitary gland, and by the intranasal use of sprays and tampons saturated with a potent preparation of double strength solution of pituitary or ampules of pitressin were all without avail. The use of a snuff made from desiccated whole pituitary gland was also ineffective, not the slightest relief being obtained from any of these procedures. The use of amidopyrine according to Scherf seemed to offer some hope.

The patient, H. B., is a man, 6 feet (183 cm.) in height and weighing 160 pounds (72 Kg.). Before the onset of the present illness he was under my care for a period of three years for various minor throat and respiratory infections. His previous history was devoid of any illness having a bearing on his present condition.

June 7, 1931, he consulted me for frequency of urination and polyuria. These symptoms started on May 15, 1931, after a mild intestinal upset for which he had taken a vigorous cathartic. Since that time he had been obliged to urinate every half hour and he passed large quantities of colorless urine each time. He also had to get up five or six times nightly to void. Formerly he perspired freely even in winter. This had been so troublesome that he had consulted a physician for relief. Since the onset of his illness, however, he had never noticed the slightest perspiration.

Physical examination revealed no abnormality. The urine had a specific gravity of from 1.001 to 1.003 on more than twenty examinations made at various times during the course of a few days. There was never any sugar or albumin present. The microscopic examination was negative. The intake and output of fluid was measured for one week. The average figures were an intake of 6,500 cc. and an output of 6,200 cc.

The blood pressure was 120 systolic, 80 diastolic. A roentgenogram of the skull showed a normal sella turcica. The Wassermann test was negative. The blood sugar was 88 mg. per hundred cubic centimeters and the urea nitrogen 13 mg.

Eye-ground examination showed normal fundi. There was no contraction of the color fields. A reexamination of the fundi and color fields in August, 1932, more than a year later, revealed no change. An examination of the nasopharynx for the remains of Rathke's pouch was negative. This was done

in order to rule out the possibility of pressure on the pituitary from cystic changes in a persistent pouch

The diagnosis established, treatment was begun with the hypodermic use of double strength solution of pituitary. This produced immediate relief of symptoms. An injection of 1 cc. just before bedtime gave complete relief until noon the next day. The first specimen of urine passed in the morning showed a specific gravity of 1.018. His sleep was uninterrupted by the necessity to void.

Eventually ampules of pitressin were substituted, as the double strength solution of pituitary produced cramps a short time after the injection. The only ill effect noticed from these injections was an intense blanching of the face, which lasted for about two hours following the use of either solution of pituitary or ampules of pitressin.

On this regimen the patient was comfortable, and only occasionally when he had some important engagement was it necessary for him to repeat the dose at 6 p. m. His appetite was good but not voracious. His weight remained stationary for over a year. During this time his fluid intake was on the average 4,500 cc. and his output was very nearly the same.

In August, 1932, after the appearance of the article by Scherf, the use of amidopyrine was instituted. Fifteen grains (1 Gm.) was given immediately before retiring. For the first time since the onset of his illness he was able to go through the entire night without an injection without having to urinate five or six times. The first specimen in the morning showed a specific gravity of 1.009. This effect was repeated on the three successive nights. On the fifth day, however, he noticed that his thirst was increased and he had to void much more frequently. This is in accord with the experience of Scherf, who noticed that the effect of the drug wore off in from three to ten days in different individuals. The effect returned, however, if the drug was discontinued for twenty-four hours.

At present my patient uses 15 grains (1 Gm.) of amidopyrine every night for three nights and the fourth night uses one ampule of pitressin. He also takes 15 grains of amidopyrine at noon. This keeps him as comfortable as the daily dose of pitressin formerly did. On this schedule his average fluid intake is about 4,500 cc. and the output is about 4,000 cc.

The relief from constant hypodermic medication on the score both of convenience and of expense makes this plan of treatment appreciated by the patient. The embarrassment of a ghastly white face following injection of pitressin during the day is relieved. The only side-effect of the amidopyrine in this patient is a transient light headedness for a short time after taking the drug. The urine is colored an intense orange by the comparatively large dose of amidopyrine.

PANCREATIC FAT NECROSIS FOLLOWING SUBTOTAL THYROIDECTOMY

W. ROSS MORRIS, M.D., ANN ARBOR, MICH.

Pancreatic fat necrosis is a somewhat uncommon condition. Especially is it rare for it to occur following an operative procedure and to be a factor in the production of death in such a case. It would therefore seem that the following case is of sufficient interest to justify its report.

Opie¹ states that Wulff (1902) and Fabyan (1907) have each reported cases of pancreatic fat necrosis in which no lesion in the pancreas has been found. Opie suggests in these cases a localized lesion of the pancreas, so slight as to escape notice. Warthin (1904) reported a case of pancreatic fat necrosis about an aberrant gland. The occurrence of fat necrosis produced by intestinal fluid containing the fat-splitting enzyme of the pancreas cannot be excluded.

REPORT OF CASE

History—Mrs. A. H., white, aged 56 entered the hospital complaining of goiter and shortness of breath. A goiter had been present for twenty years. This had gradually increased in size for several years, then remained about the same size

for several years, and again increased in size during the six months immediately before admission to the hospital. In general, her health had been excellent until one year before admission, during which time she had noted ease of fatigue, marked nervousness, shortness of breath, palpitation, swelling of the ankles, frequent feeling of increased body heat, and excessive perspiration. All of these symptoms had gradually become more marked, especially during the two months before admission.

Examination revealed a large adenomatous goiter involving chiefly the left lobe of the thyroid, in which cystic change had taken place, moderate generalized arteriosclerosis, arteriosclerotic heart disease and myocardial insufficiency. The blood pressure was 170 systolic and 78 diastolic. It was felt that the heart disease was partly on a thyrogenic basis as well as arteriosclerotic. The urine and blood studies were negative. The Kahn test was negative. The basal metabolic rate was -7 per cent, the pulse rate, 56. A laryngeal examination was negative. Roentgen examination of the chest showed substernal prolongation of the thyroid with compression and deviation of the trachea, calcified atheromatous changes in the ascending, horizontal and descending parts of the aorta, and apparent calcification of the aortic and pulmonic ring. The lung fields were essentially normal.

In spite of the fact that the patient was a poor operative risk, owing to the cardiovascular disease, it was decided that subtotal thyroidectomy was indicated. After six days of preparation, consisting of rest in bed and digitalization, she had markedly improved and seemed in good condition. Subtotal thyroidectomy was performed and a large, cystic adenomatous goiter was removed. The immediate postoperative condition was satisfactory and continued so for about fifteen hours. She then complained of severe, generalized abdominal pain and vomited frequently. The abdomen was moderately distended and tympanic throughout, there was marked tenderness throughout the upper part of the abdomen and peristalsis was heard. The rectal temperature was 100 F. and the pulse 110. The symptoms became worse, abdominal pain more marked, vomiting more frequent, abdominal distention increased somewhat, the rectal temperature rose to 102 F., the pulse to 146 and very weak, tenderness in the upper part of the abdomen increased, and there was a profuse cold perspiration—the picture of severe shock. There was evidence of considerable fluid in the lungs and moderate edema of the lower extremities. Death occurred thirty-eight hours after operation.

Autopsy—This revealed extensive pancreatic fat necrosis in the pancreas, mesentery, omentum and retroperitoneal adipose tissue (thrombosis of branches of intrapancreatic veins with localized necrosis involving ducts) generalized arteriosclerosis with aortic calcification, arteriosclerotic atrophy of kidneys, slight chronic glomerulotubular nephritis, passive congestion and edema of the lungs, bilateral hydrothorax, edema of the lower extremities and the brain, terminal cardiac failure with dilatation, passive congestion of all organs, Graves constitution.

From the conditions found on microscopic examination of the pancreas the pathologist gained the opinion that the pancreatic lesions were on a vascular basis, rather than having had their origin in the pathologic changes of the duct.

COMMENT

The etiology of pancreatic fat necrosis is not definitely known. However, the preponderance of evidence seems to indicate that infection in the biliary tract is at least the most important etiologic factor. In this case there was no definite evidence of previous biliary infection. The definite cause of the pancreatic fat necrosis is not apparent. It is not clear whether the intrapancreatic venous thrombosis was the cause of or the result of, the pancreatic changes. However, it seems more likely that the pathologic changes resulted from the thrombosis. But what produced the thrombosis? This cannot be answered. It is not clear that it was in any way connected with the operation or anything in the patient's condition before operation. Yet this relationship cannot be excluded, for the pancreatic lesions did develop immediately following operation and undoubtedly played a large part in the fatal termination.

DIPHTHERIA MORTALITY IN LARGE
CITIES OF THE UNITED
STATES IN 1932

TENTH ANNUAL REPORT

This report concerns the ninety-three cities dealt with in the recent article on typhoid,¹ and the rates are calculated on the basis of the population figures used in that article. The number of diphtheria deaths in each city has been reported to us by the respective health department.²

So far as we have been able to ascertain, tables 1-8 contain rates for all the years since 1890 for which diphtheria deaths are available in the records of the health departments of the respective cities or in Chapin's "Municipal Sanitation." Certain of the five-year averages for the individual cities are based on

figures for less than five of the years indicated. The irregularities have heretofore been marked by footnotes giving the missing years for each city. To clarify the tables, the specific footnotes are replaced in the present report (and the practice will probably be continued in the future) by the simple note "Incomplete data." The years that are included in the five-year averages, but for which diphtheria mortality data are lacking, are as follows: Akron, 1905, 1906, 1907, 1908, Canton, 1915, Des Moines, 1905, 1906, 1907, 1908, Erie, 1895, Fort Worth, 1918, 1919, 1920, 1921, 1922, 1923, Houston, 1902, 1903, 1904, Indianapolis, 1890, Jacksonville, 1925, Kansas City, Kan., 1910, 1911, Kansas City, Mo., 1910, 1911, Long Beach, 1920, 1921, Louisville, 1890, Miami, 1925, Peoria, 1907, 1908 and the first four months of 1909, Salt Lake City, 1890, 1891.

The preceding articles were published in THE JOURNAL, Sept. 20
1924 p 918 April 25, 1925, p. 1269 April 3 1926 p 1005 April 30

M A 100 1491 (May 13) 1933

2. It should be noted that the figures include all deaths of diphtheria that have occurred within the city limits of nonresidents as well as residents. In some instances this undoubtedly has exaggerated the impression of the amount of diphtheria in a community, but all competent statisticians are agreed that 'the attempt to eliminate the deaths of nonresidents would often result in an understatement of the true mortality' (Bureau of the Census Mortality Statistics 1912, p 13). Cities in which one third or more of the reported diphtheria deaths are stated to have occurred are indicated in tables 1 & 8. A further discussion of the problem of the nonresident in diphtheria statistics was given in the report last year.

HARBORVIEW DIVISION

The New England group (table 1) again makes a new low record (3.65), some individual cities registering a low rate for the third consecutive year. The Connecticut municipalities, led by New Haven, have had in recent years a notably smaller diphtheria mortality than the Massachusetts cities. Bridgeport, after several years of an intensive control campaign, makes a par-

ticularly fine showing, the single diphtheria death reported being that of a nonresident. The diphtheria mortality in Boston is less than for the year before, though not quite equaling its banner year of 1930. Lowell experienced a considerable increase in diphtheria in 1932. In Worcester the mortality from the disease seems to be slowly creeping up.

The cities in the Middle Atlantic states (table 2) better their excellent record of 1931 and easily maintain

TABLE 3—*Death Rates of Nine Cities in South Atlantic States from Diphtheria (Including Croup) per Hundred Thousand of Population*

	1932	1931	1930	1929	1928	1927	1926	1925	1924	1923	1922	1921	1920	1919	1918	1917	1916	1915	1914	1913	1912	1911	1910	1909	1908	1907	1906	1905	1904	1903	1902	1901	1900	1899	1898	1897	1896	1895	1894	1893	1892	1891	1890	1889	1888	1887	1886	1885	1884	1883	1882	1881	1880	1879	1878	1877	1876	1875	1874	1873	1872	1871	1870	1869	1868	1867	1866	1865	1864	1863	1862	1861	1860	1859	1858	1857	1856	1855	1854	1853	1852	1851	1850	1849	1848	1847	1846	1845	1844	1843	1842	1841	1840	1839	1838	1837	1836	1835	1834	1833	1832	1831	1830	1829	1828	1827	1826	1825	1824	1823	1822	1821	1820	1819	1818	1817	1816	1815	1814	1813	1812	1811	1810	1809	1808	1807	1806	1805	1804	1803	1802	1801	1800	1799	1798	1797	1796	1795	1794	1793	1792	1791	1790	1789	1788	1787	1786	1785	1784	1783	1782	1781	1780	1779	1778	1777	1776	1775	1774	1773	1772	1771	1770	1769	1768	1767	1766	1765	1764	1763	1762	1761	1760	1759	1758	1757	1756	1755	1754	1753	1752	1751	1750	1749	1748	1747	1746	1745	1744	1743	1742	1741	1740	1739	1738	1737	1736	1735	1734	1733	1732	1731	1730	1729	1728	1727	1726	1725	1724	1723	1722	1721	1720	1719	1718	1717	1716	1715	1714	1713	1712	1711	1710	1709	1708	1707	1706	1705	1704	1703	1702	1701	1700	1699	1698	1697	1696	1695	1694	1693	1692	1691	1690	1689	1688	1687	1686	1685	1684	1683	1682	1681	1680	1679	1678	1677	1676	1675	1674	1673	1672	1671	1670	1669	1668	1667	1666	1665	1664	1663	1662	1661	1660	1659	1658	1657	1656	1655	1654	1653	1652	1651	1650	1649	1648	1647	1646	1645	1644	1643	1642	1641	1640	1639	1638	1637	1636	1635	1634	1633	1632	1631	1630	1629	1628	1627	1626	1625	1624	1623	1622	1621	1620	1619	1618	1617	1616	1615	1614	1613	1612	1611	1610	1609	1608	1607	1606	1605	1604	1603	1602	1601	1600	1599	1598	1597	1596	1595	1594	1593	1592	1591	1590	1589	1588	1587	1586	1585	1584	1583	1582	1581	1580	1579	1578	1577	1576	1575	1574	1573	1572	1571	1570	1569	1568	1567	1566	1565	1564	1563	1562	1561	1560	1559	1558	1557	1556	1555	1554	1553	1552	1551	1550	1549	1548	1547	1546	1545	1544	1543	1542	1541	1540	1539	1538	1537	1536	1535	1534	1533	1532	1531	1530	1529	1528	1527	1526	1525	1524	1523	1522	1521	1520	1519	1518	1517	1516	1515	1514	1513	1512	1511	1510	1509	1508	1507	1506	1505	1504	1503	1502	1501	1500	1499	1498	1497	1496	1495	1494	1493	1492	1491	1490	1489	1488	1487	1486	1485	1484	1483	1482	1481	1480	1479	1478	1477	1476	1475	1474	1473	1472	1471	1470	1469	1468	1467	1466	1465	1464	1463	1462	1461	1460	1459	1458	1457	1456	1455	1454	1453	1452	1451	1450	1449	1448	1447	1446	1445	1444	1443	1442	1441	1440	1439	1438	1437	1436	1435	1434	1433	1432	1431	1430	1429	1428	1427	1426	1425	1424	1423	1422	1421	1420	1419	1418	1417	1416	1415	1414	1413	1412	1411	1410	1409	1408	1407	1406	1405	1404	1403	1402	1401	1400	1399	1398	1397	1396	1395	1394	1393	1392	1391	1390	1389	1388	1387	1386	1385	1384	1383	1382	1381	1380	1379	1378	1377	1376	1375	1374	1373	1372	1371	1370	1369	1368	1367	1366	1365	1364	1363	1362	1361	1360	1359	1358	1357	1356	1355	1354	1353	1352	1351	1350	1349	1348	1347	1346	1345	1344	1343	1342	1341	1340	1339	1338	1337	1336	1335	1334	1333	1332	1331	1330	1329	1328	1327	1326	1325	1324	1323	1322	1321	1320	1319	1318	1317	1316	1315	1314	1313	1312	1311	1310	1309	1308	1307	1306	1305	1304	1303	1302	1301	1300	1299	1298	1297	1296	1295	1294	1293	1292	1291	1290	1289	1288	1287	1286	1285	1284	1283	1282	1281	1280	1279	1278	1277	1276	1275	1274	1273	1272	1271	1270	1269	1268	1267	1266	1265	1264	1263	1262	1261	1260	1259	1258	1257	1256	1255	1254	1253	1252	1251	1250	1249	1248	1247	1246	1245	1244	1243	1242	1241	1240	1239	1238	1237	1236	1235	1234	1233	1232	1231	1230	1229	1228	1227	1226	1225	1224	1223	1222	1221	1220	1219	1218	1217	1216	1215	1214	1213	1212	1211	1210	1209	1208	1207	1206	1205	1204	1203	1202	1201	1200	1199	1198	1197	1196	1195	1194	1193	1192	1191	1190	1189	1188	1187	1186	1185	1184	1183	1182	1181	1180	1179	1178	1177	1176	1175	1174	1173	1172	1171	1170	1169	1168	1167	1166	1165	1164	1163	1162	1161	1160	1159	1158	1157	1156	1155	1154	1153	1152	1151	1150	1149	1148	1147	1146	1145	1144	1143	1142	1141	1140	1139	1138	1137	1136	1135	1134	1133	1132	1131	1130	1129	1128	1127	1126	1125	1124	1123	1122	1121	1120	1119	1118	1117	1116	1115	1114	1113	1112	1111	1110	1109	1108	1107	1106	1105	1104	1103	1102	1101	1100	1099	1098	1097	1096	1095	1094	1093	1092	1091	1090	1089	1088	1087	1086	1085	1084	1083	1082	1081	1080	1079	1078	1077	1076	1075	1074	1073	1072	1071	1070	1069	1068	1067	1066	1065	1064	1063	1062	1061	1060	1059	1058	1057	1056	1055	1054	1053	1052	1051	1050	1049	1048	1047	1046	1045	1044	1043	1042	1041	1040	1039	1038	1037	1036	1035	1034	1033	1032	1031	1030	1029	1028	1027	1026	1025	1024	1023	1022	1021	1020	1019	1018	1017	1016	1015	1014	1013	1012	1011	1010	1009	1008	1007	1006	1005	1004	1003	1002	1001	1000	999	998	997	996	995	994	993	992	991	990	989	988	987	986	985	984	983	982	981	980	979	978	977	976	975	974	973	972	971	970	969	968	967	966	965	964	963	962	961	960	959	958	957	956	955	954	953	952	951	950	949	948	947	946	945	944	943	942	941	940	939	938	937	936	935	934	933	932	931	930	929	928	927	926	925	924	923	922	921	920	919	918	917	91 of Camden brings up at the foot of the list, as it did in 1931, this city also had the highest typhoid rate in the group in 1932.¹

Several of the South Atlantic cities (table 3) show notable improvement over preceding years, Richmond, Baltimore and Wilmington all having low rates. The three Florida cities Tampa, Jacksonville and Miami, on the other hand, report rates that indicate an excessive prevalence of diphtheria. It is a little surprising to find that Miami in 1932 records more than double the diphtheria rate in New York.

The East North Central cities (table 4), which in 1925-1929 had the highest average diphtheria rate of any section of the country, have made the greatest relative improvement and now are second only to the Middle Atlantic cities. Particularly notable in this group stands the city of Cleveland. The reduction in diphtheria in recent years in Detroit, and particularly in Chicago, is quite spectacular. South Bend, also in this group, is apparently the only city in the country which in 1932 lost none of its citizens from either diphtheria or typhoid. Dayton and Fort Wayne seem to have had an unusual prevalence of the disease, and Peoria has apparently had a real epidemic.

The East South Central cities (table 5), as a whole, do not show much change from the preceding year. Louisville, Birmingham and Nashville having very sim-

Utica	0.0	Syracuse	0.5
Yonkers	0.0	New Haven	0.6

ilar rates to those for 1931. Knoxville, however, had next to the highest rate in the table, being exceeded only by Dallas.

Although the group rate for the cities of the West North Central states (table 6) does not register much change, individual cities such as St. Paul, Minneapolis, Kansas City, Mo., and particularly St. Louis, show

steady improvement St Paul and Duluth indeed report their only deaths as among nonresidents Des Moines and Wichita seem to have had small epidemics

Six of the eight West South Central cities (table 7) show an increase in 1932 over 1931 and the group as a whole has an average rate of 8.16 in 1932, as against 5.93 in 1931 Fort Worth and Dallas the latter with the highest rate among the ninety-three cities, seem to

† Lacks data for South Bend

‡ Lacks data for Oklahoma City for 1922 and 1930

be the chief sufferers from this disease It is curious that diphtheria should now be so relatively prevalent in this region, since from 1900 to 1920 the cities of the Southwest had considerably less diphtheria mortality than the rest of the country

The Mountain and Pacific group of cities (table 8) shows an increase in the diphtheria rate from 2.71 for 1931 to 3.43 for 1932, Taconia being the only city in the group to register a reduction Seattle continues to have a lower rate than Portland, and San Francisco than San Diego and Los Angeles

At the present time, the cities in the United States that have a cold winter and a generally "bad climate" are faring considerably better with respect to diphtheria than the Southern cities and the climatic resorts of the Western coast Long term records however, will be necessary for the proper interpretation of these somewhat surprising records

Council on Pharmacy and Chemistry

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT
PAUL NICHOLAS LEECH, Secretary

CITROCARBONATE, ACETONYL, SALICYONYL, BROMIONYL, BROMIONYL WITH ACETYL-SALICYLIC ACID, BROMIONYL WITH BARBITAL, OINTMENT SCABICIDE, KEROLYSIN, SUPER D COD LIVER OIL, PRODUCTS OF THE UPJOHN COMPANY, NOT ACCEPTABLE FOR N N R

For many years the Upjohn Company of Kalamazoo, Mich., has exploited to the medical profession and indirectly to the public a large number of pharmaceutical preparations many have been marketed with unwarranted and extravagant therapeutic claims some with therapeutically suggestive names, not a few are of semisecret composition This firm has developed promotion through the agency of "detail men" to a high state of efficiency Many physicians attest the insidious persuasiveness of these advance agents, their generosity with samples the brilliant spectrum of their line of pills the profusion of their "literature." Some preparations of the Upjohn Company have in a few communities largely replaced standard nonproprietary products of equal or greater merit to the financial benefit of the firm and to an equivalent financial detriment to the public

The following are examples of some of the more widely used Upjohn preparations space does not permit discussion of all the unacceptable products of this firm

Citrocarbonate—This is stated to be "An alkaline effervescent mixture of organic salts of Lime Potassium Sodium and Magnesium properly balanced" and was formerly known as "Tribasic Citrocarbonate" According to the advertising matter "Each teaspoonful (about 60 grains, 4 Gm.) when dissolved presents approximately 1½ grains (0.8 Gm.) free sodium bicarbonate 28 grains (1.8 Gm.) sodium and potassium bicarbonates as citrates and tartrates 2½ grains (0.162 Gm.) calcium lactate with correct proportions of phosphates, sulphates and magnesium Contains about 2% sodium chloride" Nowhere in the extensive advertising material on this product is there a complete quantitative statement of composition Just how sodium and potassium bicarbonates can be represented in solution as citrates and tartrates is not quite clear (presumably the latter salts are formed during effervescence the citrates would be oxidized in the body to carbon dioxide and water but the tartrates are poorly absorbed and hence would be practically unavailable and are not readily burned in the body at best) It must indeed have been an epoch-making discovery that indicated the "correct proportions" of phosphates sulphates and magnesium, unfortunately this great contribution has not yet come to the attention of the Council It is said that "Citrocarbonate contains all those elements which normally preserve physiological alkalinity so proportioned as to approximate normal blood plasma ratios" Just what value there can be in the administration of ions in fixed proportion in this way is not apparent, the food intake would immediately and considerably disrupt this exquisite balance The body economy has somehow managed these millions of years to maintain its own ionic equilibrium The Council knows of no indications in conditions in which ordinarily alkaline therapy is of benefit for supplying salts other than those of sodium and occasionally those of calcium Contrary to the emphatic statements of the firm there is no reliable evidence that harm has come from the intelligent administration of sodium bicarbonate alone When alteration of the normal ionic equilibrium does

occur in disease the normal ratios of cations would no longer maintain. If we follow the Upjohn logic correctly, the way to restore the equilibrium is to administer the ions in the ratios occurring in normal blood obviously, if some cations are relatively more deficient than others the former should be supplied in *relatively greater quantities*. Citrocarbonate still throws the burden of compensation on the selective physiologic mechanisms of the body. It is therefore quite absurd to administer so "carefully adjusted" a mixture when the regulatory organs must perform their selective functions anyway.

In the advertising literature occurs the following statement:

Making it Easier to Drink Enough Water

Because of its palatability Citrocarbonate may be used to advantage in much diluted form when a large or measured intake of water is one of the requirements. It frequently becomes quite a monotonous proceeding for a patient to drink say 8 or 12 glasses of water a day. It aids matters considerably to instruct that half of these drinks be taken with a teaspoonful of Citrocarbonate in a full glass of cold water. This gives variety and adds palatability and snap to the draught while the diuretic and systemic effects of the water are correspondingly enhanced.

It is well known that the administration of large quantities of water, when this is done therapeutically or when it is necessary to replenish the water loss of profuse sweating may result in symptoms of alkalosis, owing to a lack of chloride. It is also well known that the addition of small quantities of sodium chloride to the drinking water renders it sufficiently palatable and prevents or alleviates the distressing symptoms. In fact the latter is now so widely appreciated that it is standard practice among blast-furnace workers, miners and others who must work in surroundings of high temperature yet for the effective table salt, physicians are urged by the Upjohn Company to substitute the proprietary Citrocarbonate which contains only 2 per cent of sodium chloride and enough base considerably to enhance the induced alkalosis!

To many persons Citrocarbonate affords a not unpleasant beverage in fact it may be said to appeal to some palates not wisely but too well. This is particularly true in these days of widespread belief in the efficacy of alkaline therapy in the prevention of colds influenza and related disorders. In this the Upjohn Company has not been entirely guiltless witness:

"Citrocarbonate
— to prevent
— to abort
— to alleviate
"COUGHS and COLDS"

In fact, in its earlier days, Citrocarbonate aspired to the virtues of a panacea.

ALKALIES are of such general usefulness in infections of various kinds that a tentative use of Citrocarbonate should be worthwhile in baffling cases of doubtful diagnosis.

In other words, when in doubt, don't find out! Try Citrocarbonate!

And even in the most recent literature of this firm this alkaline mixture is indicated as being therapeutically useful in a variety of diseases, the list of which resembles in scope if not in detail, the index to a modern textbook on medicine. Yet, in extenuation, the qualifying footnote should be quoted:

Not that the list is exhaustive nor that alkali is always indicated. The thought is to set forth the great range of possible usefulness for Citrocarbonate when applicable. Alkaline therapy is not for any disease as such it is really an attempt to reconstitute the electrolyte and water structure of the body fluids which is the basis for colloid chemistry and hence of cell function a restorative measure worthy of consideration whenever the integrity of the body fluids has been impaired by disease, drugs, diet or other cause.

Thus, with a fine similitude of modern, if somewhat obscure, science do we progress! It is indeed unfortunate that the Upjohn Company considers it necessary to invoke the hocus-focus of its particular brand of colloid chemistry as a background for the exploitation of a shotgun mixture.

Space is not available for discussion of the many other extravagant claims made for this preparation.

The Council declared Citrocarbonate unacceptable for inclusion in N. N. R. because it is a mixture of semisecret and unscientific composition, containing an excessive number of active ingredients (rules 1, 2 and 10), marketed with extravagant and unwarranted therapeutic claims (rule 6) under a misleading and uninformative name (rule 8).

Acetonyl—One might judge from this name that this preparation is in some way related to acetone yet it is said to constitute "Granular Effervescent Alkaline Acetylsalicylates." Each teaspoonful ('about 60 grains') of this mixture in 6 ounces of cold water is stated to represent 'Acetylsalicylic Acid (as the sodium salt) 7½ grs together with the bicarbonates, citrates, and tartrates of sodium, potassium, calcium and magnesium having a combined systemic alkalizing effect equivalent to 33.5 grs sodium bicarbonate.' In the 1931 catalogue it was claimed: 'In most conditions in which acetylsalicylic acid is used its combination with alkaline treatment is more effective than is the acetylsalicylic acid itself in tablet form. This is explained in part by its more prompt absorption. Of greater importance is the fact that acidosis is commonly present in conditions calling for acetylsalicylic acid, and where it does exist its tendency is to increase pain and irritability. The formula is so calculated as not only to insure absorption and elimination of the acetylsalicylic acid without drawing on the alkaline reserves of the body, but to provide a systemic alkalizing effect as well.' Again the specter of acidosis! There is no good evidence that the administration of alkalis with salicylates modifies their systemic effects in any way; it does diminish gastric irritation. Certainly the equivalent of 33½ grains (2.2 Gm.) of sodium bicarbonate for each 7½ grains (0.5 Gm.) of acetylsalicylic acid must be considered excessive. There is, furthermore, no satisfactory evidence for the statement that 'acidosis is commonly present in the conditions calling for acetylsalicylic acid.' The quantities of the various alkaline salts present are not declared; hence the preparation must be considered semisecret; it is apparently also unnecessarily complex.

In the 1933 catalogue it seems no longer necessary to explain the principles that guided the Upjohn Company to the preparation of this mixture; the following statement is now deemed sufficient: 'Acetonyl is analgesic and antipyretic and is particularly useful in such affections as neuralgias, headaches and similar conditions as well as in colds, influenza, and fevers.' And, one may add, so are ordinary tablets of acetylsalicylic acid.

Not a few individuals are hypersensitive to salicylic acid preparations. Many if not most, such individuals sooner or later learn of this idiosyncrasy and therefore avoid such medication or at least take it only in tolerable dosage. Here we have another salicylate mixture marketed under a name nondescriptive of its active component, self-medication to the point of toxicity might readily occur, particularly as the solution is not unpalatable to many persons.

For this reason and for others identical with those that determined the Council's action in the case of Citrocarbonate, Acetonyl was declared unacceptable for N. N. R.

Salicionyl—This is claimed to be "A granular effervescent salt presenting sodium salicylate in such a way as to reduce the incidence of those unpleasant features which complicate the use of salicylates alone. Each heaping teaspoonful (about 60 grains) when dissolved, presents approximately 10 grains of sodium salicylate with 20 grains of free alkaline bicarbonate, plus a mixture of the citrates and tartrates in proper balance to assure systemic alkalization. The alkalizing effects of Salicionyl, nearly equal to those of Citrocarbonate, are helpful in meeting the acidotic [sic] tendencies which mark the conditions for which salicylates are given, such as rheumatic fever, tonsillitis, and other infections known to have an acidotic background [italics ours]."

It is obvious that the objections made for Acetonyl apply also to this preparation. One wonders why the firm should market this mixture if the advantages claimed for Acetonyl are all they were stated to be.

The Council therefore declared Salicionyl unacceptable for New and Nonofficial Remedies.

Bromonyl—This is another granular effervescent salt. It is stated, 'Each teaspoonful (about 60 grains) when dissolved in six ounces of cold water, presents a palatable carbonated draught approximately equivalent to Sodium Bromide 9.50 grs, Calcium Bromide 3.75 grs, Potassium Bromide 2.50 grs. The solution has a systemic alkalizing effect (as citrates and tartrates) equivalent to 27 grains of sodium bicarbonate.'

The idea that a mixture of several bromides is of greater therapeutic usefulness than sodium bromide alone was long ago discarded, yet a number of pharmaceutical manufacturers seem not yet to be aware of it. Like the preceding Upjohn preparations, Bromonyl is of semisecret composition, and the name is objectionable. Although it is recommended in dosages equivalent to from 60 to 75 grains (4 to 5 Gm.) of bromine per day, no mention is made of the possibility of bromidism—which indeed has occurred following the use of this preparation. Its palatability would be likely to lead patients to indulge in it too freely. The rationale of combining large quantities of alkali with bromide medication is not apparent.

Bromonyl is not acceptable for New and Nonofficial Remedies because it is apparently an unnecessarily complex mixture of semisecret composition (rules 1, 2 and 10) sold under a misleading name (rule 8).

The Upjohn Company also markets *Bromonyl with Acetylsalicylic Acid* and *Bromonyl with Barbitol*, these are even less acceptable than the parent mixture; they involve fixed ratios of bromide with acetylsalicylic acid in one case and of bromide with barbitol in the other. Because of differences in the rates of elimination of these substances from the body, dosage in fixed ratio is irrational.

Ointment Scabicide—Ointment Scabicide is said to contain 'the polysulphides of potassium'. No statement is made as to which or how much of the four potassium polysulphides are present in this ointment. The alkaline sulphides have long been known as depilatories although the potassium salts are not as effective in this respect as some of the others, they are consequently effective also in dissolving the superficial layers of the skin. Aside from the decidedly unpleasant odor associated with the liberated hydrogen sulphide, one would hesitate to anoint the entire body with a preparation having such keratolytic properties. It is admitted in the advertising that more than one application may produce dermatitis; one is inclined to believe that, in some persons, even one application might cause inflammation; a member of the Council has seen severe generalized dermatitis from self medication with this mixture. The claimed advantage of rapid action would hardly compensate for the possible deleterious effects of this ointment.

Scabicide was declared unacceptable for New and Nonofficial Remedies because it is a semisecret preparation (rules 1 and 2) apparently of unscientific composition (rule 10), marketed with a therapeutically suggestive name which has frequently led to self medication by the public (rules 4 and 8).

Kerolysin—Another therapeutically suggestive name. Kerolysin is said to contain 'Acid Benzoic 12%, Acid Salicylic 6%, Thymol 1¼% in a suitably adapted ointment base'. This is obviously nothing but a modification of the well known Whitfield's ointment certainly not deserving a proprietary name.

This very potent preparation (the benzoic and salicylic acid contents are even greater than those of the Whitfield ointment) has been responsible in many cases for severe local tissue destruction particularly in patients who were self medicated. Furthermore Kerolysin is recommended as 'a valuable aid as a deodorant antiseptic and antipruritic in the treatment of a number of conditions which may or may not be dependent upon fungicidal infection such as sweaty feet, soft corns, bromidrosis, dyidrosis, hyperidrosis, axillary irritation, or eczema, pruritis and etc.

Needless to say the use of such a corrosive preparation in any of these conditions deserves hearty condemnation.

It is also stated 'Let the patient use persistently until sound skin is regenerated.' Those who have had experience with local medication with the active components of Kerolysin know the severe tissue destruction that follows their 'persistent' use.

The Council declared Kerolysin to be unacceptable for New and Nonofficial Remedies because it is an unessential modification of a well known mixture, marketed with unwarranted therapeutic claims under a proprietary, therapeutically suggestive name, uninformative of its essential constituents (rules 4, 6 and 8).

Super D Cod Liver Oil—Super D is said to be assayed by the U S P method for vitamin A potency and to contain not less than 25,000 units per ounce. It is said also to represent 'a vitamin D potency of not less than 10,000 units per ounce, controlled by the McCollum line test, and secured by special methods of selection and by the addition as required of vitamin

D." It is stated to contain a small amount of flavoring material. The vitamin D assay units are not qualified as to magnitude and hence are essentially meaningless (although judging from the description in the recent advertising literature these are probably intended to mean A D M A units). It is not stated how the vitamin D is added, whether as viosterol or as a concentrate of cod liver oil, or by irradiation or in some other way. The preparation appears, therefore, to be semisecret. The name may or may not indicate that this may be a fortified oil, it requires careful reading of the description to determine this.

It seems that the oil may or may not be fortified as the firm deems it expedient; it is claimed that 'The Super D of this date [November 1931] has a natural potency of at least 10,000 units of vitamin D per ounce'.

The name "Super D" conveys an implication of superiority not warranted by any evidence available to the Council; this preparation appears to be no better than—if as good as—products accepted for New and Nonofficial Remedies and sold under much more modest and informative names and of which the potency is clearly stated. Physicians would do well to restrict their cod liver oil prescriptions to those preparations listed in New and Nonofficial Remedies, of which there is an ample number in this way they may be assured of the use of products the potencies of which have been definitely established and are indicated in unmistakable terms. They would also be dealing with firms which market their products in accordance with the rules of the Council.

Super D Cod Liver Oil was declared unacceptable for New and Nonofficial Remedies because of its semisecret composition and indefinitely designated vitamin potency (rules 1 and 2) and because of its objectionable name (rule 8).

Committee on Foods

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

RAYMOND HERTWIG Secretary

SUNRISE PANCAKE FLOUR

Manufacturer—Concordia Milling Company, Concordia, Kan.

Description—A self rising pancake flour containing soft and hard wheat flours, sodium bicarbonate, calcium acid phosphate, dextrose salt and powdered skim milk.

Manufacture—The ingredients are mixed in a batch mixer and automatically packed in bags.

Analysis—(submitted by manufacturer) —

	per cent
Moisture	12.3
Ash	4.4
Fat (ether extraction method)	1.2
Protein (N x 6.25)	10.7
Crude fiber	0.6
Reducing sugars as invert sugar	0.4
Sucrose	1.8
Carbohydrates other than crude fiber (by difference)	70.8

Calories—3.4 per gram 97 per ounce

Claims of Manufacturer—For making pancakes and biscuits

EDDY'S PAN DANDY BREAD

EDDY'S TWIST LOAF

Manufacturer—Eddy Bakeries, Helena, Mont.

Description—White breads made by the sponge dough method (method described in THE JOURNAL, March 5, 1932, p 817) prepared from patent flour, water, sucrose, powdered skim milk, butter, salt, yeast and yeast foods containing calcium sulphate, ammonium chloride, sodium chloride and potassium bromate and buttermilk, calcium phosphate and ammonium tartrate.

Claims of Manufacturer—Conform to the United States Department of Agriculture definition and standard for white bread. The only shortening used is butter.

WHITE HOUSE NATURAL BROWN
RICE FLAKES

(FLAVORED WITH SUGAR, SALT AND MALT)

Manufacturer—Standard Rice Company, Inc., Houston, Texas*Description*—Cooked, flaked and toasted brown rice, flavored with sugar salt and malt syrup*Manufacture*—Natural brown rice containing the natural bran with the formula proportion of sucrose, salt, malt syrup and water is steam cooked in revolving sealed steel drums. The cooked mass is broken into separate granules, which are dried to a moisture content suitable for their flaking between steel rolls. The flaked rice is toasted in revolving ovens, is passed over screens to remove fine material, and packed in wax-paper wrapped cartons*Analysis* (submitted by manufacturer) —

	per cent
Moisture	3.1
Ash	4.3
Fat (ether extraction method)	2.0
Protein (N \times 5.95)	8.5

Protein (noncaffeine and nontheobromine N \times 6.25)	5.6
* Cocoa red	0.2
Theobromine and caffeine	0.01
Carbohydrates (essentially sucrose lactose and maltose) (by difference)	22.6

* Ulrich method (J. A. O. A. C. 1916 page 550)

Calories—1.7 per gram 48 per ounce*Claims of Manufacturer*—For the preparation of chocolate and malt flavored milk drinks and other food recipe preparationsWHITE ROCK BRAND CRYSTAL
TABLE SYRUP

(CORN SYRUP FLAVORED WITH ROCK CANDY SYRUP)

Manufacturer—Wheeler-Barnes Company Minneapolis*Distributor*—Andrew Kuehn Company Sioux Falls S. D.*Description*—Corn syrup flavored with rock candy syrup (the same as White Oak Brand Crystal White Syrup 85 per cent Corn Syrup 15 per cent Rock Candy Syrup THE JOURNAL, Oct 15, 1932, p 1353)

PRINCESS CORN MEAL

Manufacturer—Blanton Milling Company Indianapolis*Description*—Corn meal practically free from corn germ and bran. The same as Evans E-Z Bake Corn Meal (THE JOURNAL, March 18, 1933, page 819)

EZEMADE BISCUITS—A MIX

Manufacturer—Zanol Products Company, subsidiary to the American Products Company, Cincinnati*Description*—Self-rising flour containing patent flour (bleached), vegetable shortening sucrose, powdered skim milk, salt, sodium acid pyrophosphate, sodium bicarbonate and calcium acid phosphate.*Manufacture*—The ingredients in definite proportions are thoroughly mixed in a batch mixer and packed in wax paper inserts in wax paper wrapped cartons. The shortening used is

specially modified to increase its stability against the development of rancidity. The product has been tested for rancidity after six months at ordinary room temperature and at 35 C, no rancidity developed under these conditions

Analysis (submitted by manufacturer) —

	per cent
Moisture	10.2
Ash	3.6
Salt	1.5
Fat (ether extraction method)	12.8
Protein (N \times 6.25)	7.6
Crude fiber	0.2
Carbohydrates other than crude fiber (by difference)	65.6

Calories—4.1 per gram 116 per ounce*Claims of Manufacturer*—Requires only the addition of liquid for the preparation of biscuit dough

REPORTS OF THE COMMITTEE

THE COMMITTEE HAS AUTHORIZED PUBLICATION OF THE FOLLOWING
REPORTS
RAYMOND HERTWIG Secretary

NOT ACCEPTABLE

CERTAINTY HEALTH BRAN

The Beaver Valley Milling Company, Des Moines, Iowa submitted to the Committee on Foods an "all bran" product prepared from wheat called "Certainty Health Bran"

Discussion of Name and Label—The name Certainty Health Bran and the prominent label claim "For your health's sake" signify that this bran will assure health to the user, a type of claim no more warranted for bran than for any other food, no food provides or assures health. A complete diet adequate in all food essentials is necessary for health, but health depends on many other factors than nutrition. The claim that the product is 'sterilized' is not in keeping with the method of preparation described by the manufacturer. A sterilized food is free of viable organisms. It is further stated that 'many doctors insist on the use of bran as an aid to digestion and the best known of nature's stimulants to aid the functioning of the bowels as it cleanses the digestive organs and eliminates the poison which often clogs the system'. Doctors do not insist on the use of bran as an aid to digestion, bran is not a digestive aid. The attributing of a claim of this nature to doctors is especially a misleading presumption. It is appropriate to claim that constipation due to insufficient roughage in the diet will yield to bran eaten regularly. Bran is not 'the best known of nature's stimulants to aid the functioning of the bowels' nor can bran be depended on 'to cleanse the digestive organs'.

The name and claims are inappropriate, misinformative and misleading. The manufacturer after being advised of the Committee's report has not shown willingness to change the name or claims. This product will therefore not be listed among the Committee's accepted foods

NOT ACCEPTABLE

JOHNSTON GRAHAM CEREAL DOTS
JOHNSTON GRAHAM CRACKERS

The Robert A. Johnston Company, Milwaukee, submitted to the Committee on Foods a cereal called "Johnston Graham Cereal Dots," prepared from patent flour whole wheat flour, sucrose, malt extract, lard, brown sugar, molasses, baking soda, salt, annatto coloring, ammonium bicarbonate, imitation vanilla (vanillin and coumarin), magnesium carbonate and sodium sulphate, and a cracker called "Johnston Graham Crackers" prepared from patent flour, whole wheat flour sucrose, malt extract, lard, brown sugar, molasses, baking soda, salt, honey, annatto coloring ammonium bicarbonate, imitation vanilla (vanillin and coumarin), magnesium carbonate and sodium sulphate.

Discussion of Names, Label and Composition—The names "Graham Dots" and "Graham Crackers" signify that whole wheat is the only farinaceous ingredient. This is contrary to the fact since whole wheat is in much smaller proportion than white flour in the manufacturing formula. The term "graham" is associated with ground whole wheat or ground whole wheat products as indicated by the United States Department of Agriculture definitions and standards for whole wheat flour

and whole wheat bread. In these definitions "whole wheat flour" and "whole wheat bread" are synonymous with 'graham flour' and 'graham bread'. According to the names, the public can rightfully expect whole wheat flour to be the sole wheat ingredient of the cereal and crackers. The added annatto golden coloring gives a color simulating that of a whole wheat product and thereby would create the impression of a greater whole wheat content than is actually present and increases the misleading nature of the names. These are not a true graham cereal or a true graham cracker but a white flour-graham cereal and a white flour graham cracker and should be named accordingly. The sodium sulphite and magnesium carbonate components are not essential or appropriate ingredients of foods. The label statement 'with milk or cream they are rich in bone building calcium' indicates that the Cereal Dots are rich in calcium, which is incorrect and misleading. The milk will provide essentially all the calcium but not the cereal. The names and label claims are misinformative and deceptive, and the added magnesium carbonate and sodium sulphite ingredients are inappropriate, unnecessary components of foods.

The manufacturer was informed of the Committee's report but is unwilling to change the names for business reasons or eliminate the sodium sulphite from the formula. These Graham Crackers and Cereal Dots will therefore not be listed among the Committee's accepted foods.

NOT ACCEPTABLE

HEALTH-E ICE CREAM CONES

The Illinois Baking Corporation, Chicago submitted to the Committee on Foods an ice cream cone called 'Health-E Ice Cream Cones' prepared from flour, sucrose cocoa, shortening, tapioca, chocolate syrup, dried milk, salt, imitation vanilla and certified coloring.

Discussion of Name and Claims—The name "Health-E Cones" implies the presence of specific health values. The cones are no more healthy or by virtue of composition related with health than are any other wholesome foods. Names of this character lead to misleading 'health food' advertising, as exemplified by the claims "individually wrapped for health's sake" and 'contains vitamin D for health' used for these cones. The manufacturer has not furnished information to substantiate a vitamin D claim nor do the ingredients of the cones justify such a claim.

The manufacturer was advised of the Committee's report but is unwilling to change the name for business reasons. These Health E Cones will therefore not be listed among the Committee's accepted foods.

NOT ACCEPTABLE

PETRA'S LAXO BREAD

The Petra Baking Company, Olean N Y submitted to the Committee on Foods a bread containing white, whole wheat and rye flours, sweetened condensed skim milk, wheat bran, pulverized flax seed sucrose, salt, yeast and malt syrup.

DISCUSSION OF NAME AND LABEL

The name 'Laxo' does not identify the ingredients which differ from those of the usual breads. The public is entitled to know the composition of the compound foods it consumes. A descriptive statement identifying the unexpected ingredients should accompany the trade name a procedure which tends to prevent misleading and misinformative advertising. The prominent label claim "Eat Laxo Bread regularly and eliminate constipation" implies that this bread will correct constipation due to any cause. The bread furnishes more indigestible residue than does white bread but less than whole wheat bread, the product, therefore, may be expected to be helpful for counteracting constipation due to insufficient roughage in the diet but not to constipation due to other causes. To inform the users of the bread properly, an appropriate claim is that Laxo Bread eaten regularly will aid in counteracting constipation due to insufficient bulk in the diet.

The company was advised of the Committee's recommendations but has displayed no willingness to comply, this bread will therefore not be listed among the Committee's accepted foods.

NOT ACCEPTABLE

CREAMO AND BUTTER-NUT BREAD BRANDS

The Muller Bakeries Inc., Grand Rapids, Mich, submitted to the Committee on Foods several brands of white breads with the trade names "Creamo" and 'Butter-nut' containing patent flour, water, lard, salt, powdered skim milk, yeast, malt syrup and a yeast food containing calcium sulphate, ammonium chloride, sodium chloride and potassium bromate.

DISCUSSION OF NAMES

Butter-Nut Brand—The name "Butter-Nut" presumably indicates that the bread contains either butter and nuts' or butternuts and in such quantity as to give the product distinctive physical and nutritional characteristics because of such ingredients and different from the customary white bread. The baking formula contains neither butter, nuts nor butternuts. The name is considered inappropriate and misleading.

Creamo Brand—The name "Creamo" implies the presence of cream in substantial quantity in the baking formula and sufficient to give the bread qualities and nutritional values not possessed by the usual white bread. Cream is not an ingredient and skim milk is the only milk product constituent. The name is inappropriate and misleading.

The bakeries were advised of the Committee's recommendations but they are not willing to change the brand names. These breads will therefore not be listed among the Committee's accepted foods.

NOT ACCEPTABLE

PATCH'S SUGAR OF MILK (LACTOSE)

The E L Patch Company, Boston, submitted to the Committee on Foods a canned lactose of high purity called Patch's Sugar of Milk (Lactose).

Discussion of Label—The container label presents explicit infant feeding formulas for infants of from 1 to 9 months. The promulgation of feeding formulas in lay advertising is considered to be in conflict with the best experience, authoritative judgment and basic principles in infant feeding. The feeding of an infant by routine feeding formulas and instructions distributed by food manufacturers, or according to directions printed materials, or advice of any person other than the attending physician who can personally observe the condition of the baby may seriously endanger the health of the infant. The feeding of the baby during the first year is of fundamental importance to its health, wrong feeding may be disastrous. Every infant, the breast fed and doubly so the artificially fed, should be under the supervision of a physician experienced and skilled in the care and feeding of infants. The manufacturer when informed of these opinions expressed himself as unwilling to remove the feeding formulas from the container label for merchandising reasons. Patch's Sugar of Milk (Lactose) will therefore not be listed among the Committee's accepted foods.

NOT ACCEPTABLE

BUTTER-NUT BREAD

The Gravem Inglis Baking Company, Inc Stockton Calif, submitted to the Committee on Foods a white bread made by the sponge dough method, called "Butter-Nut Bread," composed of flour, water, shortening, dry skimmed milk, yeast, salt and a yeast food containing calcium sulphate, ammonium chloride sodium chloride and potassium bromate.

Discussion of Name and Advertising—The name "Butter-Nut Bread" indicates that the bread contains either butter and nuts' or 'butternuts' and in such quantity as to give the product distinctive physical and nutritional characteristics because of such ingredients and different from the customary white bread. The baking formula does not contain butter, nuts or butternuts. The name is considered inappropriate, misinformative and misleading.

The manufacturer, when informed of this opinion expressed himself as unwilling to change the name in accordance with the Committee's recommendations. This bread will therefore not be listed among the Committee's accepted foods.

Please send in promptly notice of change of address giving both old and new always state whether the change is temporary or permanent. Such notice should mention all journals received from this office. Important information regarding contributions will be found on second advertising page following reading matter.

SATURDAY, MAY 20 1933

A NEW COMPARISON OF URINE AND PERSPIRATION

In an older period of clinical medicine, the skin and the kidneys were usually considered together as eliminatory organs for the body. Consequently, when difficulties in the excretory functions of the renal structures arose it was not uncommon to spur the skin to act in a vicarious role as far as possible. Diaphoretics or sudorifics were administered in many instances of nephritis with the hope that the resulting profuse perspiration might help to remove "waste products" that were ordinarily represented in the urine. Presently it began to be realized that although sweating may help to bring about loss of water, as in the anasarca of nephritis, and that it unquestionably facilitates the removal of heat, the amount of saline and nitrogenous waste thus carried away does not bulk large. For many years, therefore, little attention was paid to the components of sweat other than water. Perspiration was associated primarily, as it doubtless deserves to be, with the heat regulation of the body.

From time to time, however, records of the composition of the sweat, freed from epidermal debris as far as possible, have revealed the presence of familiar components of the blood and urine. Urea, uric acid and lactic acid, for example, were unmistakably recognized, even though the proportions found were small. Dextrose has been detected in cases of diabetes mellitus. Such information suggests that under certain circumstances the skin functions in an eliminatory manner. In fact, it has been stated that in pathologic disorders such as cholera and uremia the sweat glands may excrete urea in such amounts that examination of the skin may disclose crystals of the substance. Recently Mosher¹ made comparative analyses of urine and sweat collected simultaneously from man. When persons whose bodies had been washed thoroughly were placed in sweat chambers maintained at from 40 to 50 C (104 to 122 F), 250 cc (about half a pint) of sweat could easily be obtained in little

longer than half an hour. Qualitatively, perspiration was found similar to urine in composition, though the relative amounts of the various components in the two solutions varied considerably. Urine is a much more concentrated solution, containing from three to five times the amount of total solids and from five to nine times the amount of organic matter.

It has been pointed out by Mosher that, although much attention has been directed to the study of the chemical components of human urine and blood with the aim of establishing relationships between the presence of certain components and variations in the percentages of the normal constituents with pathologic disorders, few similar investigations have been conducted with perspiration. This is indeed surprising, he adds, when it is considered that many dermatologists ascribe certain skin diseases to unknown chemical substances or to an abnormal balance of the usual constituents in the sweat. Mosher argues that, before any useful investigations on the influence of perspiration on the etiology of skin disorders can be scientifically instituted, more exact information as to the normal components of sweat is required, particularly the nitrogen fraction. His study is a contribution in this direction.

THE RELATION OF TRAUMA TO PARALYSIS AGITANS

Since James Parkinson wrote his classic "Essay on the Shaking Palsy" (1817) there has been much discussion as to the cause and pathogenesis of paralysis agitans. Recently the relation of trauma to the development of Parkinson's syndrome has been discussed in French and German literature. Ruhemann¹ found that of thirty-five cases of paralysis agitans seven were traceable to trauma. Oppenheim² wrote that injuries to the head, sacrum or an extremity, especially a crushing injury of the nerves, may be the cause of paralysis agitans. Catola³ comments on the difficulties in evaluating the relation between trauma and disease of the nervous system from the medicolegal point of view but admits that craniocerebral trauma may provoke vascular lesions, necrosis and neuroglial proliferation.

Recently Naville and de Morsier⁴ made an extensive report on trauma as a factor in Parkinson's disease. They studied two groups of cases: first, a series of thirty-two patients with a history of cranial trauma; second, a group of forty-two patients subjected to peripheral trauma. They classified the cases of cranial trauma as follows: (1) cases of trauma followed by parkinsonism apparently at least due to contusional encephalitis; (2) cases of aggravation by trauma of existing Parkinson's disease, encephalitis or hereditary

predisposition, (3) cases of trauma during the development of an infectious encephalitis followed by paralysis agitans, (4) cases of psychic trauma. They note that the disease may appear from several days to three months or more after a cranial trauma, most frequently cerebral concussion. In most instances the tremor and hypertonia appeared in the midst of other symptoms usual after cranial trauma, such as headache, cervical rigidity, fatigue, vertigo or insomnia. There were also mental abnormalities, particularly depressive states with nocturnal agitation. In the series of peripheral injuries studied by Naville and de Morsier, various kinds of trauma were concerned, such as contusions, fractures, dislocations, muscle tears, electrical shock, infected wounds and crushing injuries. Once begun, the syndrome did not differ from the nontraumatic type of paralysis agitans. Usually there was not complete recovery between the time of the trauma and the appearance of first symptoms of paralysis agitans which most frequently developed several days or weeks after the injury. The tremor and hypertonia always appeared first in the injured limb, and when two regions were hurt simultaneously the tremor appeared in the two areas at the same time. As concerns age, 21 per cent occurred in persons under 40 years, while in the non-traumatic type of paralysis agitans only 10 per cent were under this age. Mental disturbances were absent in patients who developed paralysis agitans after peripheral trauma. The extension of the symptoms occurred on the injured side.

Minovici, Paulian and Stanesco⁵ are more conservative in their interpretation of the part of trauma in causing paralysis agitans. They think that it may be a contributory factor but not necessarily a direct cause. They point out that there is as yet no agreement as to the nature and localization of the lesions. The muscular incoordination in this disease has been ascribed to lesions in the extrapyramidal tracts and basal ganglions. However, pathologic changes have been found in other parts of the brain, so that this aspect of the subject is still controversial. They affirm that it is rare to encounter all the elements of Parkinson's disease directly after trauma, further, that the olivopontocerebellar syndrome and inflammation of the striate bodies may be confounded with Parkinson's disease, which has an identity all its own. The importance of emotional shock as a cause of this disease is stressed, patients have been observed in whom the classic symptoms of paralysis agitans occurred soon after a psychic shock. It is acknowledged by these writers that trauma, after all, may favor the development of paralysis agitans by indirect effects of contusion, shock, hemorrhage or meningeal irritation. While the relation of trauma to paralysis agitans still remains an open question, the problem certainly deserves further and close study on account of its practical importance.

COMMERCIAL ASPECTS OF BACTERIOPHAGE THERAPY

The premature commercial exploitation of "bacteriophage" has no doubt induced expenditure of considerable sums for therapeutically inert preparations of bacteriophage-lysed bacterial filtrates. Laboratory scientists suggested the subtle and misleading name "bacteriophage." True, certain bacterial filtrates introduced into a limited volume of fluid culture medium will in many cases cause the suspended bacteria to die. The dead bacteria disintegrate. After disintegration a hundred times the original lytic titer is demonstrable in the culture medium, together with numerous other autolytic products.

Ignoring possible enzymes, hormones, genes and other growth factors, imagination pictured this lysis as the result of a hypothetical bacteria-digesting virus. A specifically active lytic agent of this character would logically not affect other factors in the animal body. It was argued that it might penetrate to the remotest corner of infected tissues in search of its specific diet. The well known fact that test-tube lysis does not take place in the presence of gelatin, egg white or numerous other colloids was disregarded. The well confirmed evidence that similar inactivations take place in the presence of mucus, fibrin, pus, blood serum, erythrocytes, fixed tissue cells and certain urinary crystalloids was also ignored by commercial interests, in spite of the fact that voluminous data have been published during the last twelve years.¹

The commercially promoted reading matter also carefully evaded references to the well confirmed evidence that limitation of volume is a necessary factor in test-tube lysis. In other words, "bacteriophage" has no appreciable injurious effects on homologous bacteria until the extrabacterial concentration of bacteriophage is raised to a certain critical level.² Publication of this fact might have suggested to prospective purchasers that the necessary critical concentration could rarely be reached or maintained in any tissue supplied with a capillary circulation, or in any urinary or cerebrospinal space with its constant lavage with new fluid.

Under the numerous test-tube conditions in which lysis does not occur, "mutation" or "adaptations" of the exposed bacteria take place, with the production of bacteriophage-resistant strains. These strains cannot be lysed even under most favorable test-tube conditions. The commercial literature failed to announce that 90 per cent of all typhoid bacilli freshly isolated from typhoid stool or typhoid blood are bacteriophage-insusceptible variants. One also seeks in vain for any reference to bacteriophage anaphylaxis or to antitherapeutic "negative phases," the well known dangers and contraindicants with certain other protein mixtures or bacterial vaccines.

¹ A historical outline is presented by Colvin, M. G. *J. Infect. Dis.* 51: 527 (Nov. Dec.) 1932.

² Limitations of Bacteriophage Therapy, editorial. *J. A. M. A.* 96: 693 (Feb. 28) 1931. 98: 1190 (April 2) 1932.

Competent investigators who have made impartial and conscientious efforts to determine the clinical value, limitations and dangers of the Twort transmissible lysin marvel at the policy of suppression of scientific fact in the promotion of bacteriophage preparations. If data suggesting limitations and dangers had been suitably set forth in advertising prospectuses, clinical trials might have been limited to certain well defined pathologic conditions, leading eventually to official endorsement, whereas the Council on Pharmacy and Chemistry has not yet accepted such preparations. Moreover, there is a rapidly growing resentment and distrust of the whole bacteriophage promotion, which certainly will delay final clinical evaluation.

Premature exploitation of the Twort lysin is by no means an isolated example of this short-sighted policy. The opsonic index was successfully sold to the medical profession, long before its technical errors were assayed, before any critical test was made of the assumed quantitative parallelism between specific opsonic index and specific immunity. Perhaps a million doses of leukocytic extract were injected before any quantitative tests were attempted to prove that such injection causes anything more than a borderline reaction of negligible therapeutic value. "Anti-cold vaccines" were widely sold commercially and even yet the etiologic factor of common colds is unknown and the evidence of usefulness doubtful. The Council on Pharmacy and Chemistry is a safe guide to follow at a time when all sorts of untried therapeutic plausibilities are being launched on the medical profession.

Current Comment

DANGER IN INTERNAL ADMINISTRATION OF SILVER PREPARATIONS

A timely warning against uncontrolled or indiscriminate use of silver preparations in internal medication has just been uttered by Knack¹ of Hamburg. While the toxic effects of chronic poisoning with silver are not in themselves alarming, the discoloration of the skin, especially that of the face, is unsightly and may seriously interfere with the pursuit of occupation. In the past, silver nitrate was extensively utilized in the treatment of the diseases of the nervous system and of the gastro-intestinal tract. The occasional occurrence of argyrosis as well as a growing conviction that the therapeutic effect of silver nitrate was inferior to other remedial substances lessened its use greatly. Then, with the development of new combinations of silver came a revival of interest in silver therapy. At the same time, manufacturers exploited such products in advertising campaigns. The silver content of some of these preparations is not always to be known from their proprietary names. The indiscriminate attitude toward silver preparations may be due to the fact that the

younger generation of physicians is not familiar with argyrosis. Knack describes two recently observed cases. One patient had taken the not inconsiderable dose of 9 Gm of silver nitrate, which was prescribed for a gastro-intestinal disturbance during the years 1920-1922. The symptoms appeared characteristically late, after a lapse of three years. The diagnosis was made from the typical blackish gray discoloration of the skin and was further confirmed in histologic sections of the skin by the new spectro-analytic method of Walther and Werner Gerlach of Basel. A special predisposition undoubtedly plays a part and occasionally a small dose is capable of producing argyrosis, as is evident from the case reported by Jacksch in which the patient received only 12 Gm of silver nitrate.

GLYCERIN AS FOOD

If it is assumed that the average daily intake of fat in the present-day diet approximates 100 Gm, this foodstuff will liberate about one-tenth its weight, or 10 Gm, of glycerin (chemically designated glycerol) in the alimentary tract as a consequence of the lipolytic digestive changes. Glycerin also finds its way into the gastro-enteric canal from other sources, it is mixed with certain commercially processed foods, is present in some pharmaceutical preparations, and is sometimes fed as such, offering through its sweetness a substitute for sugar. It seems almost gratuitous to question the physiologic wholesomeness of a normal digestion product of one of the familiar nutrients, yet this seems to have been done from time to time in the case of glycerin. There are, indeed, published records of untoward effects from glycerin, but in these it is not always clear whether the introduction has been by way of the alimentary tract or whether perchance the product has been administered parenterally. It would not be surprising if subcutaneous or intravenous use of glycerin should lead to untoward consequences. As a recent writer has remarked, numerous examples could be cited of innocuous and even indispensable materials occurring in the gastro-intestinal tract which kill if injected subcutaneously, intraperitoneally or intravenously. Examination of medical writings with this in mind reveals that it is essentially in instances of parenteral administration of glycerin that injurious consequences have been reported. An extensive reinvestigation² of the subject, involving the feeding of varying amounts of glycerin to different species, including man, has recently been completed at the department of physiology of the University of Chicago. This shows that glycerin as such can safely be incorporated into the regimen in far larger proportions than that in which it is liberated from even large quantities of dietary fat. It readily replaces carbohydrates, having about the same caloric value. In the case of man, glycerin was fed over a period of fifty days in amounts as large as 110 Gm daily without any demonstrable

¹ Johnson V. E., Carlson A. J. and Johnson Adelaide. Studies on the Physiological Action of Glycerol on the Animal Organism. *Am. J. Physiol.* 103: 517 (March) 1933.

undesirable effects. It did not affect the red or white cell counts or the hemoglobin content of the blood. The temperature was unaffected, and neither the basal metabolism nor the uric acid output was significantly changed. These items are mentioned because they have been the subject of dispute. There have been reports in the past of phenomena—sleeplessness, talkativeness and excitement—resembling manifestations of alcoholic inebriation. The Chicago physiologists, referring to glycerin feeding, somewhat whimsically remark that thus far no signs of addiction have displayed themselves in their subjects.

Medical Economics

PRIVATE GROUP PRACTICE

[This series of investigations by the Bureau of Medical Economics will be published in THE JOURNAL in three parts. The second part will appear next week.]

The original source of information for this study was a questionnaire sent to 1,949 secretaries of county medical societies asking for certain information as to the number of groups within their jurisdiction and the nature of the practice in which the groups are engaged. Two hundred and sixty-six secretaries reported the existence of one or more groups within the jurisdiction of their societies. The total number of groups so reported was a little over 500, the indefiniteness was due to the fact that some reports gave '8 or 10' and similar estimates. Later investigation showed that many of these could not be properly classified as examples of group practice, a difficulty that is partially due to the fact that it is almost impossible to formulate any clear or standard definition of a medical group. Moreover, most of those listed were calling themselves "clinics" and were being so considered in their localities.

The replies to this questionnaire give the most complete view of the attitude of members of the medical profession toward various questions involved in group practice and its results that has yet been obtained. That this view is as fair and impartial as could well be obtained is shown by the fact that the proportion of secretaries of county medical societies who stated that they were themselves members of groups is at least equal to the proportion of members of groups in these societies to nonmembers.

One of the questions on the schedule, the answers to which are of significance in determining the probable development and extent of group practice in the near future, was, "Is the number of groups increasing?" Two hundred thirty-five secretaries replied to this question. Of these, 192 said "No" and 42 "Yes." The majority of "No's" would seem to be sufficiently large to indicate that in those localities where group practice already exists it shows slight tendency to increase its scope.

Another point on which there has been much discussion is whether group practice reduces the cost of medical care to the patients. This information was sought through the question, "Has group practice as conducted in your community contributed a practical method of providing medical service at reduced costs to the patient?" Of 230 secretaries who replied to this question, 170 said "No" and 60 "Yes." This would seem to justify the conclusion that of those secretaries who have had an opportunity to judge of the working of group practice the overwhelming majority are of the opinion that it has not reduced costs to the patient.

The next question gives an opportunity to explain these simple negative and affirmative replies. It asks, "In what way has group practice reduced the costs of medical service to the patient?" It may be well to call attention to the fact that this is somewhat of a leading question, as it assumes that group practice has 'reduced the costs of medical care to the patient.' There were 159 replies, of which 69 simply emphasized their

previous negatives by saying "none," "not at all," "in no way," etc., while 12 said that the costs have been increased to the patient by group practice, and 8 gave noncommittal answers, such as 'do not know,' 'opinions differ,' etc. Some of the explanations given of these answers are helpful in understanding the attitude of those who replied.

Reduced overhead—increases individual practice by referring to members of group.

Did not reduce but allowed better service.

Costs patient more money through unnecessary roentgenologic and laboratory work.

Doubt if costs have been reduced. Group practice has been responsible for a higher type of service and keeps the medical man up on his toes more.

Increased unnecessary expense.

Owing to excessive amount of unnecessary laboratory service general consensus is that there has been no saving for the patient.

Excessive overhead holds the costs high.

Has not reduced. More charge to the patient. Examination in clinics cost \$25 to \$50 and in doctor's office \$10.

Not in one case the group not being highly specialized.

In no way. It has reduced our individual expense.

There are fifty-three replies that may be interpreted as indicating an opinion that in some way group practice has reduced the cost of service to the patient, although a few of these answered the previous question in the negative. Thirty-eight listed reduced or no extra charges and greater facility for consultations within the group as a reason for believing that charges have been reduced. The reports of four groups located in small cities cited the saving of traveling expenses by patients who would otherwise go to larger centers of population. Nine stated that a centralized laboratory saves on cost of diagnostic services. Four mentioned possible savings due to a reduction of overhead and an increased number of patients who can be cared for by the same staff.

The affirmative replies may be fairly summed up as making a slight claim for lower charges for equivalent care but insisting that superior facilities and extra consultation service can be furnished without extra charge.

The next question has some indirect bearing on this problem of greater economy of group practice. It reads, "State definitely the objects for which groups are formed in your community (reduction of individual overhead expense, joint ownership of costly equipment, easier access to special consultants or for other reasons)." One hundred and twenty-eight secretaries made some sort of comment on this question. In the analysis that follows it must be remembered that many gave several objects and are therefore counted more than once.

Of these, eighty-eight say that the objects listed in the question were those sought in forming the group. Many of these made additional comment and others who replied to this question gave additional reasons. Eighteen emphasized the possibility of financial gain for the members making such statements as:

'Probably for increasing income of owners.'

'Making money for owner; others are on salary basis.'

'Personal gain' (4 replies in substance).

To obtain greater momentum for more business.

'To make more money—that's all. To appear big, talk big, charge big.'

Of the total replies there were forty-four that mentioned improved relations and conditions of practice helpful to the physicians who were members. Of these nine stress the opportunity to go away for vacations or graduate study without disorganization of practice and loss of patients. There are eleven replies that mention certain personal and professional conditions which attracted physicians to groups:

'Opportunity to develop along special line.'

'Personal protection or special benefits accruing therefrom.'

Better chance for consultation and improvement.

To hold together—and aloof from others—a certain group of friends.

'Practice specialty and keep in touch with other fields.'

More convenient to practice scientific medicine.

Congenial cooperation of social and professional relationship.

Personal satisfaction to physician of being able to limit work to one or two branches.

'A place to practice medicine, surgery and obstetrics as it should be done and as cheaply as possible.'

'Physician is able to emphasize his own specialty and can have group of trusted friends and specialists around him.'

A few additional replies do not quite fall in the foregoing classification because they give greater stress to personal and financial reasons, some of which are evidently due to local

situations Three say the group was formed to reach a wider radius of patronage and to meet competition with metropolitan centers One said "To increase individual practice by referring to members of group" Another gave as an object "Lessened initial expense to new-comer in group" Another gave "Reduce dead-beats—overcome local competitive friction" A fourth said that it was "easier to do industrial work."

Thirty-seven replies emphasized benefits to patients as among the objects which led to the formation of groups Of these, fifteen said "better service," and seven others added such qualifications as "quicker," more complete," and "more efficient." Others went into such details as

Necessity of medical accomplishment for which no single individual is equipped mentally or physically

To afford patient medical service by one familiar with case in absence of member without additional cost to patient.

Provide somewhat isolated community with well balanced organization to care for any case too difficult for general practitioner

Elimination of travel to city for consultation. Fees are less than city fees for special work.

To render twenty four hour service for industrial accidents

It seems probable that these replies are sufficiently comprehensive, inclusive of members and nonmembers and distributed geographically as to include practically every reason that has led to the establishment of groups and to give as accurate a picture as is reasonably possible of the motives for the formation of groups

The next four questions were designed to bring out the attitude of the local profession toward group practice Again the impartiality of these replies rests on the fact that a considerable proportion of the secretaries answering were members of groups and that both sides—if there were two sides—were therefore represented This also, to some extent accounts for the sharply antagonistic opinions

The first of these questions asked for a direct answer of "Yes" or "No" to the question "Is this type of medical practice satisfactory to the majority of physicians in your community?" Of 148 who answered only with a direct affirmative or negative, 87 said "Yes" and 61 "No" The comments of those not answering directly added little to the information sought in the following questions "If satisfactory in what respect does your society favor group practice? If unsatisfactory, state the undesirable features of group practice"

To the first question, which assumes the satisfaction of the county medical societies with group practice forty-three secretaries made neutral, noncommittal replies such as "has taken no action" "nothing said," "no expression," and "not interested"

There are twenty-three replies that indicate division or active opposition within the medical society Samples of these comments are

Not satisfactory but tolerated because it interferes little with individuals

Society does not favor

Impossible to tell O K with those doing group practice.

Sentiment is divided

Objected to by some

They do not particularly favor it but they just do not oppose it

Is favored in negative sense—tolerated

Many of our men will not even share a building with another practitioner

Society favors group practice as long as those in the group stay confined to their specialty and do not encroach on private practice of general practitioner

No complaint of serious nature

A number are satisfied—others not

The society does not exactly favor group practice nor is it against it

We are divided on the subject. I believe the majority favor individual practice

Some opposition on competition of groups

Satisfactory to the one group

Clinic groups are not particularly criticized but tend to be isolated from general run of practitioners

There are twenty-three replies that may be fairly interpreted as indicating that the secretary considered the opinion of the county medical society to be favorable to group practice. Some of the reasons given for this attitude are

Develops better type of men in profession

Society respects group practice because more complete diagnosis due to better laboratory facilities and cooperation within group

Better feeling among doctors with greater efficiency for individual doctors.

Cooperates with all other members of the society

Better medicine practiced

'Allows community to have hospital

Better facilities for diagnosis and treatment'

Staffs of both groups are all members of the society and their association has the good will and approval of other members of the society

There is a marked tendency toward group formation and it is favored by the society

Has raised standard of practice in community

It makes for stronger better equipped individuals Makes for stronger medical center Draws patients from larger area

It will be seen that even when asked to state reasons why the medical society favored group practice more than two thirds of those replying gave noncommittal or critical comments and that more than half of the secretaries failed even to express a vote on the direct question of whether group practice is satisfactory to a majority of the physicians in the community where it exists which would seem to justify the conclusion that the general attitude of those members of the profession who have come into direct contact with such practice is hostile or sharply critical The twenty-three positively favorable replies are fewer than the number of secretaries who are members of groups This does not imply that all such favorable replies are from group members for this is not true, but rather that there is a recognition by both members and nonmembers of this general critical or hostile attitude of members of the profession to group practice.

This conclusion is strengthened by the replies to the request "If unsatisfactory state the undesirable features of group practice" Sixty-five secretaries listed one or more such features These fall largely into certain definite classes The largest number criticized the lack of cooperation of groups with other practitioners The nature of these may be judged from the following examples

Eliminates privileges of consultation between members and non members

Too much close communion

Stirs up dissension

Try to keep all work in their own hands"

Isolation of groups

Patients referred to clinic do not return to physician

Unsatisfactory to physicians outside group—competition is strong and control of patients more difficult.

There is unavoidable jealousy of outside members

Limits choice of consultants

Creates factionalism

The establishment of cliques creating prejudice and jealousy"

We feel that they are not always ethical as far as their relations with outside physicians is concerned

Hinders full cooperation and general good will among physicians.

It is at times unfair because any patient can get confirmation of diagnosis right or wrong Outside doctor is therefore always wrong

There are a number of charges of unethical practices, such as

Unethical competition

Group advertising—solicitation by business manager

High pressure salesmanship

Aggressiveness in procuring patients—indirect methods of advertising

Because of cost of operation has to go after business in many ways unsatisfactory to profession

Has tendency to monopolize and commercialize the practice

Tendency to publicity in the press.

Too much aggression and free advertising

They have inexperienced men and tell public they have specialists They set themselves up as better physicians and surgeons They advertise directly and indirectly by virtue of these groups

Tendency of this group to disregard commonly accepted ethical conduct and to cater to irregulars.

Other criticisms allege excessive claims of special ability of group members and the designation as specialists of those who lack proper qualifications for the title

Untrained practitioners place themselves before public as specialists

Often inexperienced physicians

Does away with individual diagnosis

Each group cannot have best specialists yet they keep patient.

Tendency to overrate individual attainments of group

Men are unqualified for respective specialties Inadequate diagnostic facilities as laboratory

A few cite dissensions within the group as an undesirable feature

'Internal trouble is all I hear of

Internal strife.

Group splits in poor times

Jealousy among members of group

A different type of criticism is directed at the relation of the group to the patients Seven replies charge that the cost to

patients is increased and four that excessive and unnecessary treatments are given. Additional comments along this line follow:

- Does not offer any benefits in service or equipment
- No benefit from family physician's records and knowledge of individual
- No free choice of physician
- Tends to remove close personal contact with patient
- Tending to stress surgery the easiest profit to base diagnosis on
- laboratory findings rather than careful physical examination and to make 80 per cent of the common run of patients share the expense of the 20 per cent actually needing specialized care

The eleventh question was designed to obtain the opinion of the secretaries as to the attitude of the public toward and any special advantages of group practice in rendering service to patients. The question reads:

'Has group practice proved to be more satisfactory to the patients who have used it than individual general or special practice?' This was to be answered by 'Yes' or 'No' and was followed by the question, 'In what respect is group practice of greater benefit to the patient?'

There were 147 replies to this question. Of these fifty-three said 'Yes,' and the comments of eleven others indicated an affirmative answer—a total of sixty-four. There were forty-one who said 'No' and nine others whose comments indicated that they did not consider group practice more satisfactory to the patient than individual practice—a total of fifty. Thirty-three who replied were unable to express a definite opinion, giving such answers as 'Do not know,' 'Cannot tell' and 'Opinions differ.'

The answers to the second half of the question 'In what respect is group practice of greater benefit to the patient?' in some ways duplicated replies to some of the previous questions but from a somewhat different angle. Fourteen said 'better' or 'quicker' or 'more thorough service' at 'reduced' or 'no additional cost.' Ten stressed the opportunity and convenience of consultation.

Other replies were:

- Greater facility in handling specialties
- Patient will be treated by specialist much earlier
- Specialties are more successful and charges are not so great
- The patient has the benefit of several opinions in diagnosis and is not so apt to be exploited in surgical procedure
- Patient benefits from more accurate diagnosis and general access to varied and costly equipment—men are better up on their specialties since they limit the field of their activities and have enough work to justify it.
- Patients better able to meet bills
- The individual doctor has more equipment with which to work and time is saved for him in consultation and laboratory work
- For the difficult case group practice is the best because all special examinations can be conducted within the group
- He can have everything necessary done at one place and with the least loss of time. Usually total cost is less
- It gives the patient the benefit of the combined physical and mental resources of the clinic at a reduced cost

The final question reverses the attitude of the previous one and asks 'If you believe group practice does not offer any special benefits to the patients state your reason therefor.'

Fifty-one secretaries expressed an opinion on this question. Many of these replies were largely a repetition and emphasis of opinions given in reply to previous questions. Twenty insisted that cost of treatment was not reduced that it was generally increased and that in many cases this was due to excessive practice. Some of these comments follow:

- Does not reduce costs and I don't believe they do any better work.
- Increased costs due to favoring the cases
- Too expensive as a rule and too much red tape. Why run every patient through a routine when not necessary?
- Probably on the whole a better physical examination than by any other method, but usually includes much unnecessary routine examination and tests which run up costs to patient.
- Ordinary type of office patient who comes for minor ailments may be inconvenienced by the delay that seems to be necessary in handling patients in a group. This type of patient could probably be cared for in a more rapid and just as satisfactory manner by the individual practitioner
- Based on statements of patients themselves the chief objection is the cost. There is always the tendency to add successive charges and costs which are not added when the individual is used
- The expense to the patient would probably be increased because of increased overhead
- Some patients complain of cost and time taken over trivial things and the general character of the service rendered
- Instead of lessening the cost per patient it is my opinion that it tends to increase it because of the possibility of greater financial returns by consulting with the many different members of the group

It increases the medical cost two or three times usually with no better results. This has been the experience with this sort of practice in our community.

Costs are greater—more unnecessary work and laboratory examination. The individual physician will put in time and effort on the patient and ask consultation if desirable but does not call in two or three others in all cases and make unnecessary x-ray and other examinations for which the patient has to pay in the group.

Has not reduced general costs to patients. Referring of patients for consultations within one or the other group as much as possible is not always of advantage to the patient.

The group fees in this city are no less than those of individuals and consultants combined.

Increases cost of medicine. Just another form of unfair competition.

The remaining criticisms are so diverse in their character as to be difficult of classification. Taken individually they give so complete a picture of the attitude of members of the profession on this important point as to justify the quotations given.

Groups so organized are for the benefit of the doctors and not of the public.

Members do not stick to specialty. All doctors in general practice. Professional interest dissipated somewhat on account of division of responsibility.

The groups are banded together for their own benefit and try to keep all work in their own hands whether it is to the benefit of the patient or not.

Examinations by a number of physicians is rarely cheaper in a group than by individuals. The relation of the family doctor to the patient must not be lost.

Several such groups broken up after year or two. Economic distress was cause of formation.

Often some jealousy among the groups as to ownership of the patient.

Feel that patients can get as adequate attention from their doctor as from groups.

It all depends on group which is no better than its weakest sister. Nepotism enters into most groups. Often merely a feeder to head surgeon.

Each group cannot have best specialists so as they keep the patient he cannot receive the best attention. Most groups have one or two outstanding men who depend on youngsters for diagnosis—not giving patient what he is paying for. Benefit of complete examination for some is offset by unnecessary amount of something done for others.

Group practice is made up of ordinary physicians who have made no special preparation for their specialty. Many unnecessarily referred. Much time lost to patients and many physiologically ruined.

If the individual physician would give the necessary time and care to the patient the benefits to the patient would equal those of group practice. The individual physician should be more valuable as he should have a greater interest in the patient.

I am convinced that group practice would offer special benefits to the patients locally provided the proper group were assembled. The group undoubtedly offer more distinct benefits. The clinic is not balanced and the clinic is too expensive for the value of the work given.

Personally I see no benefit from group practice especially in country districts. It may be an advantage in large centers of population when as usual it is in connection with large general hospitals.

A clearly defined feature of the replies is that they are contradictory on almost every point. A possible explanation is that they do not refer to the same thing. It has been customary to discuss group practice as if it were a standardized uniform type. This may be due in part to the tendency to focus attention on the material equipment forms of organization and number of members without considering the variable human element and the personal relations within the group and with the patients and the profession which after all are the basic facts in all medical practice.

When one considers this one begins to see that medical groups vary as widely in this most important feature as the individuals who compose them and the people with whom they come in contact. Then it is possible to understand why one group is praised and another condemned.

Any form of medical practice exists for the purpose of giving a personal medical service to patients, and the vital questions concerning it are not its internal business arrangements, the methods of distributing income among its members or even the size of its equipment or the amount of capital invested. All these are secondary to the knowledge, skill, tact, integrity and other 'personal capital' possessed by the individual physicians and all forms of medical practice must be judged by this standard rather than by standards borrowed from the fields of industry and commerce.

Applying these standards as far as possible to the facts just presented it is possible to draw some conclusions. It would seem to be quite clear that the individual physicians controlling the groups have not generally succeeded in reducing the costs of medical care. They have increased it in some cases, reduced it in others and given better service for the same money some-

times and unnecessary service at other times, just as individual practitioners have done. There is nothing inherent in group practice that requires any of these policies.

When a similar standard is applied to the question of the relative attractiveness to the individual physician of group versus individual practice, one again obtains contradictory answers. If the objective is financial success, achievement depends on the individuals and the methods used. The same conclusion follows concerning those groups motivated by scientific enthusiasm, desire for more thorough service or any of the other objectives listed.

Common possession of superior equipment or facilities for consultation does not insure better diagnosis or service unless these facilities are in the hands of persons with the purpose and ability to use them for the benefit of the patient. Without this purpose and ability, elaborate equipment and multiplicity of alleged specialists result only in unnecessary duplication of work and expense to the patient.

Another set of judgments seems to depend more on whether the association of several individuals in itself creates new conditions. Sociologists have long recognized that the group tends to exhibit in an exaggerated form many of the characteristics of the individuals who compose it. A sort of "group patriotism" is developed which, unless vigilantly restricted, creates mutual hostility between the group and all outsiders. That some groups have failed to control this tendency is plainly shown by the replies indicating friction within local medical associations.

Ethical problems are always concerned with relations between individuals or groups of individuals. New ethical problems develop with each new form of association. It is, therefore, inevitable that medical groups will create such problems. This does not imply that the principles of medical ethics are changed, but only that new relations create new strains and stresses within the ethical structure.

The larger the "overhead" and the resulting "fixed charges" in any business, the greater is the pressure for expansion of the market. The pressure on a medical group with expensive equipment to seek new business in unethical ways is therefore inherently greater than on the individual practitioner. The presence of a "business manager," less sensitive to medical traditions, and compelled to justify his existence by financial standards introduces another disturbing element. The very numerical bulk of the group and its possibly conspicuous equipment tempt it to adopt forms of publicity not used in individual practice.

It should be clear that there is no inherent good or evil in business managers, equipment or the grouping of numerous physicians. These features are but instruments and the ethical questions involved concern their use by the individuals constituting the group. Ethical questions, like medical service, are personal and individual. There are no different, or additional, standards of conduct for individuals in a group from those for individuals working alone, although many lay discussions seem to assume the contrary. Advertising solicitation, excessive practice restriction or choice of physician are no different and no less reprehensible when practiced through a third person by a number of physicians in a group than by an individual practitioner.

(To be continued)

Rest and Pain.—About the middle of last century a very philosophically minded surgeon, James Hilton wrote a remarkable book, now too much neglected entitled *Rest and Pain*. He pointed out that rest was nature's method of cure for many ailments and that pain was a method of securing rest. One might almost modify a well known phrase and say "While there is pain there is hope." Not infrequently, when the vital forces are giving up a hopeless conflict pain ceases. Unfortunately, although pain is nature's danger signal and imperative demand for rest, it is not perfectly adapted to its end. Here let me put forward what I believe to be an important law of life: the response to an abnormal stimulus is never so perfectly adapted as the response to a normal one, if it were in the course of evolution the abnormal response would replace the normal one.—Brown W. L. *Rheumatism and Arthritis as a Public Health Problem*, *J State Med* 61:249 (May) 1933.

Association News

THE MILWAUKEE SESSION

Railroad Rates

The Southeastern Passenger Association, in addition to the other passenger associations previously mentioned, has announced that tickets will be sold from its territory to the annual session of the American Medical Association at one and one third fares in accordance with the regulations set down under the heading "Transportation" in the May 13 issue of *THE JOURNAL*.

The round trip rate of one and one half fares previously announced by the New England Passenger Association has been reduced to a fare and one-third for the round trip.

Section Dinner

The Section on Gastro-Enterology and Proctology has arranged to have its dinner at the Hotel Schroeder on Wednesday evening, June 14, at 7 o'clock. Dr. H. L. Bockus, 250 South Eighteenth Street, Philadelphia, is the secretary of the Section on Gastro-Enterology and Proctology.

Section Reunion Meeting and Smoker

The officers of the Section on Ophthalmology have arranged for an informal reunion meeting and smoker Wednesday evening, June 14, at about 7:30, in the Skyroom of the Plankinton Hotel. The secretary of this Section is Dr. Parker Heath, 1551 Woodward Avenue, Detroit.

ANNUAL CONGRESS ON MEDICAL EDUCATION AND LICENSURE

Twenty-Ninth Annual Meeting held in Chicago Feb 13 and 14 1933

(Concluded from page 1437)

DR. T. J. CROWE, Dallas, Texas, in the Chair

THE FEDERATION OF STATE MEDICAL BOARDS OF THE UNITED STATES

FEBRUARY 14—AFTERNOON

Regulation of the Practice of Pharmacy

H. C. CHRISTENSEN, PH.G., Chicago. Pharmacy has much the same trouble as medicine and the rest of the professions—that is, an oversupply. We discuss regulation along the same lines that you have today, and we find the same obstacles. We have made progress in pharmacy. Some physicians who see the ordinary drug store from the outside probably are not impressed with its professional appearance. After all, the educational requirements of pharmacy have been advanced until it is nearly on a par with the other professions. Thirty-eight states are now on a college graduation requirement, which means a four year course in addition to high school. We have not yet gone onto what might be called an equivalent of your premedical requirements.

In pharmacy the work of reciprocal interchange was delegated to the individual boards from 1904 to 1914, without supervision by a national office, but this plan was not satisfactory. Therefore, in 1914 a central office was established in Chicago which acts as a clearing house for reciprocal licensure. Each applicant submits a statement of his qualifications to that office on proper forms. If he is found to be eligible in the particular state in which he desires registration, an official application blank is issued to him, for which there is a fee. No member board recognizes a reciprocal application unless it is made on this official form. Thus we have had a uniform application blank for many years.

We have, I believe, greater variation in our standards for entrance to board examination than you have in medicine. Approximately forty states require college graduation at present, but in some of these exemptions still remain open. From the standpoint of the boards, the central office has increased the efficiency in handling these applications. The boards have the final decision as to acceptance or rejection of the application, but the percentage of rejections is very small.

Our association's income from dues is \$25 for each active member board, providing a budget slightly in excess of \$1,200.

per annum at present, which would not support a central office. The fairest method of meeting the association's expense, it seemed to us, was by a fee, payable by the applicant at the time of issuing the official application. Thus the actual cost of maintaining reciprocity devolves chiefly on those who receive the benefits of a reciprocal license. In the pharmacy examinations we adopted a uniform grade standard years ago—a general average of 75 per cent with not less than 60 per cent in any one subject. Some of the boards that were slow in affiliating with the association did not adopt this standard until some years later, with the result that some of their earlier registrants who were licensed with a minimum grade of 50 or 55 per cent or perhaps a general average of 70 per cent are now ineligible in some states that are holding strictly to the uniform standard. The question of reciprocity resolves itself into trusting an examiner in another state having faith in his integrity; he cannot translate his rating into absolute or arbitrary numbers—it is either a case of deeming the applicant worthy of a license and passing him, or else deeming him incompetent and denying him a license. Therefore, I am hoping that we shall soon be able to accept your liberal attitude on this question of grades by completely eliminating consideration of them in reciprocal registration.

In our system of reciprocity, any state board that affiliates with the National Association of Boards of Pharmacy agrees to give examinations at least equal to the minimum standard examination recommended by the association. The requirements specify the subjects of examination, the number of questions in each subject, and the number of subdivisions. We have forty-nine member boards interchanging licenses and recognizing one another's examinations. In this respect pharmacy has accomplished a national system of reciprocity. The pioneer work was done from 1904 to 1914. After about ten years of reading examination questions at conventions and arguing about them finally when our examination committee prepared an outline for the minimum standard examination we were ready to accept it. We had to guard against infringement of states' rights. But we were not satisfied with the old harsh rule of "equivalent state standards" which worked so many injustices. We finally worked out what we call our basic rule for reciprocity," which places the basis for reciprocity on the personal qualifications of the applicant at the time of examination instead of making the requirements of the state law the basis; namely, that the applicant is eligible reciprocally in those states in which he was eligible to sit in examination on the date of his original registration. That word *original* is important—it exempts him from any increase in requirements after his examination date. Pharmacy was the first profession to work out this personal qualification basis for reciprocity. In some states it was difficult to get the legal authorities to see the justice of accepting such an interpretation of the law and sometimes we had to amend the reciprocal clause to get the interpretation accepted.

The National Association of Boards of Pharmacy was organized for the purpose of working out a system of national reciprocity. We feel that we have accomplished a great deal. By agreeing on a national goal or standard in the form of a recommendation at our annual meetings, we have had something definite to suggest when the individual states were considering changes in their pharmacy laws. A model law was compiled; uniformity, however, is desired only in essentials. No attempt is made to enact this draft, word for word.

The most important problem confronting the public health professions today is the growing tendency toward consolidating these boards into departments of licensing, registration, and so on with the responsibility and power placed in the hands of a political director. Such consolidation has already been accomplished in five states (including Illinois) and I am informed that ten states are at present threatened with attempts to enact such legislation. The plea is of course, saving money for the taxpayers. The politicians who sponsor such measures overlook the fact that the professional boards are self-supporting. Taxpayers have never been called on for funds to support these boards; all the expense being borne by the members of the profession. Therefore the motive back of such measures is undoubtedly the realization that dwindling taxes will soon necessitate abolishment of many bureaus and

jobs; thus new offices must be created this time at the expense of the professions and the public welfare. A study of the existing consolidation departments shows that they are relatively inefficient and expensive. The economy argument is a myth, once the department is established. In one state such a department was started on a budget of \$100,000 a year (a very slight saving from the cost of operating individual boards). Twelve years later, this budget had been increased to \$300,000. A perusal of the reports of such departments finds little if any mention of law enforcement. Most of the budget is spent in licensing activities, whereas the purpose in issuing licenses is merely to have a record to aid in law enforcement. The professional boards can do little, once such a department has been established. Their powers are limited to conducting examinations and grading papers.

When the original state laws governing the practice of medicine, dentistry, pharmacy and other public health professions were enacted great care was taken to keep the professions out of politics. That safeguard is needed today more than ever. It is our duty now to fight for the right to continue to police our own professions without political interference. The public welfare demands it. Medicine alone cannot win the fight nor can pharmacy or dentistry or any other of the professions. If, however, when such measures are proposed in a given state the professions within that state will present a united front and inform not only the legislature but also the public as to the true facts in the case, we shall be successful in retaining our right to continue free from political interference.

Interstate Endorsement of Medical Licensure

DR J. N. BAKER, Montgomery, Ala. One of the most important obligations of licensure boards at present is that of investigating and rating the professional and moral integrity of candidates. More thought should be given to tests of character in the applicants who come before it. Similar tests should be encouraged for those who apply for admission to schools of medicine. These tests should include evidence of the applicant's attitude of mind toward work and his due regard for obligations and duties which have been assumed by him or imposed on him. It is believed that many brilliant minds as they progress through the elementary schools, acquire habits of indolence because their tasks, having been designed for the average child, are too easy to command their interest. Not only habits of indolence but a disrespect for educational ideals and school policies are sometimes engendered in the upper 25 per cent of the pupils because of this maladjustment. Medical schools are making a definite bid for entrance students from this group of the higher intelligence levels. All along the line, insufficient emphasis is being placed on the fact that no man can hope to adorn the practice of medicine or succeed in fulfilling his obligations to society if he fails to value and glorify his work as well as to be dignified by it. In the interest of humanity our boards of medical examination and licensure should not only undertake to test the work habits of candidates who come before them but ascend a little farther upstream in the educational field and endeavor to promote in our grade schools the safeguarding of brilliant children from the disintegration of character that results from a lack of sufficient exercise for the full quota of one's mental faculties.

Reciprocity is an existing mutual agreement between the states in question. The merits of each candidate are given individual consideration. In Alabama, few reciprocity certificates were granted prior to 1917. I use the term advisedly here because under the present arrangement, the attorney general of this state has ruled that there must exist a written reciprocal agreement with the state from which a candidate applies before a pro forma certificate can be issued. However, in Alabama trading and politics at least up to now have played no part in this method of licensure. Granted the existence of reciprocity relations, physicians are licensed on the basis of their qualifications. The experience of the federation suggests the early adoption of practical uniform medical practice acts, the education of the public to an appreciation of scientific medicine, the utilization of active cooperation from the reputable medical profession and the removal of sectional barriers against reciprocal licensure of adequately qualified

physicians regardless of the name or geographic location of the states from which they apply

One of the present barriers to uniform practice in medical licensure is found in those states which have enacted 'basic science' laws seeking to control and eliminate cult and irregular practice. Such acts require that every candidate who comes before the medical board for examination shall be given a test in the 'basic sciences' regardless of the method by which he proposes to practice the healing art. The thought behind such laws is to establish a base line of minimum requirements for all who aspire to practice the healing art, regardless of the method of treatment employed. Alabama has but one yardstick for all who assay to treat diseases of human beings, into which unit of measurement no therapy is incorporated. The application of this yardstick is vested, by law, but fairly and impartially, in a board of medical examiners, composed exclusively of regular medical practitioners, the only qualifying condition being that in the case of any applicant not of the regular school, the educational qualifications are waived. In Alabama, as in other states, many attempts have been made by the various cults to batter down these high standards, but so far without success. It safeguards the legal interest of citizens and answers effectively the charge of selfish motives put forth in cult propaganda against practitioners of scientific medicine. The disadvantages of basic science laws are easily discernible in that it complicates licensure and exacts a superfluous and unwarranted amount of work in examining candidates who have been graduated from grade A medical schools.

Owing to certain complications inevitably growing out of such a 'basic science' law, the federation has not seen fit to give it unqualified endorsement yet, in some of the states basic science legislation has aided in controlling the wholesale issuance of cult license by independent or political boards.

Should candidates who have failed before a medical board be subsequently licensed by reciprocity? Alabama has been the subject of some comment on this score in that it does not grant a pro forma certificate to any physician who has once failed before its own medical board of licensure. It has been a continuing belief of the Alabama board that the standards for reciprocity should be even higher than those for examination. With this thought in mind it is felt that this rule should receive wider observance and should certainly not be abrogated at this time by any state board.

DISCUSSION

DR ROY B. HARRISON, New Orleans, Louisiana has a straight medical board, and our reciprocity deals entirely with physicians. Our law requires that one has to be a graduate of a class A medical school graded by the American Medical Association to practice one year subsequent to licensure, and to have at least ten major subjects with an average of 75 per cent in each one. Each application for a license by reciprocity is handled as an individual case. We have some applications on file for three months before they are passed on. We found through experience that many men will move to another state for other reasons than change of climate. We find there is quite a bit behind their transferring from one state to another. We have a temporary permit to a reciprocity applicant, which gives plenty of time to investigate before we finally act on his application. We investigate him through the American Medical Association and through the place he last resided and through the place where he contemplates practicing. We require that each individual be an American citizen before we give him a license by reciprocity or by examination. We do not even consider any foreign application for reciprocity. We examine all, and we look up their credentials and so forth in Europe or wherever they come from. The Louisiana board is, I think, a bit different from some boards in that we have a straight out and out medical board and we have a few cults as any state in the United States. We have no chiropractors and the other cults are in the minority. The osteopaths have their own board. They are not allowed to use drugs in any form. I think there are only twenty-five in the state of Louisiana. The chiropodists and the opticians have a limited license. One of the principal objections to standardizing reciprocity is that one state will have a medical practice act that is more severe than that of another state. Ours has been severe, and we are going to keep it severe as long as we can.

We are going to keep it a straight medical board and prosecute all cults as they come up.

DR H. M. PLATTER, Columbus, Ohio. Ohio will accept through reciprocity, a man licensed in another state who meets the Ohio requirements for entrance to the examination at the date of his graduation and is from a school that would permit him to write the Ohio examination. There is no reason why there should be a varying standard of requirement in the several states, of men who are graduates of a class A medical school. A committee of this federation, meeting with a committee from the Association of American Medical Colleges, might work out a working agreement which could be applied to every state in the Union. It is our practice to send out about twelve letters on every applicant for reciprocity. They go to the county medical society, to physicians who are Fellows of the American Medical Association who are known to us either personally or by reputation, to the American Medical Association and frequently to some man of prominence in the town from which the man is coming.

DR C. H. EWING, Larned, Kan. I sometimes wonder whether we do not take ourselves too seriously in the matter of qualification of members in reciprocity. I see in THE JOURNAL a list of the failures from various schools and I wonder if we are qualified to pass on the ability of the students from these schools better than the heads of our universities. I sometimes wonder whether there is not something wrong with the medical board instead of the university or the students. Reciprocity is more or less of a joke in some states. In our state we have a medical board. The chiropractors have a board of their own. The osteopaths have a board. We have nothing to do with them at all. We do not permit a student to take our examination unless he is the graduate of a class A medical school. The heads of our universities know when these students are qualified to practice medicine and we rely on their judgment. For that reason we do not have any failures.

DR H. J. LEHNHOFF, Lincoln, Neb. A man seeking licensure in Nebraska by reciprocity does not have to take an examination before the basic science board. They have the privilege of passing him without an examination and in most cases do. There are difficulties with the basic science boards. I think their requirements are too high. Several years ago this federation advised the basic science boards to come to a better agreement among themselves, which I think was good advice. I do not think they should require a grade of 75 for passing when practically all of the medical boards require only 60. The board of Nebraska and the physicians in general do not want to bar students from other states. I think it is the feeling of all of us that we want a freer reciprocity. There are a lot of little things in reciprocity and licensure that we could agree on. We surely can agree on the age of the individual who is applying for licensure. We ought to agree on his citizenship but we do not. Some states require full citizenship some of them require the filing of the first papers or the second papers. If we went at this carefully, we could get together on reciprocity and all be very much happier.

DR O. G. COSTA-MANDRY, San Juan, Puerto Rico. If I am not mistaken the Alabama board does not recognize reciprocity to any individual who has failed in an examination in the state from which he came. Am I correct?

DR J. N. BAKER, Montgomery, Ala. No. We have had instances wherein a man would fail before our board, go into an adjoining state and pass that examination and come back and want reciprocity. We do not give reciprocity in those cases.

DR COSTA-MANDRY. I do not think that an examination is always a fair means of judging the ability of an individual. If an individual makes a good showing in practically every subject and flunks in one subject, one has to consider a lot of factors that one would not otherwise consider. In our board we have a special ruling for grading examination papers. We divide the subjects into two groups. Our passing mark is 75 per cent. We allow an individual to fail on one examination in each group of subjects, and if he makes an average of 75 per cent we pass him, but if he does not make the average of 75 per cent, he has the right to solicit the representation of all his papers to see whether a mistake was made in grading them. I am more inclined to think that one should consider

the cases individually on the merits of each case rather than to make a hard and fast rule and say that, if an individual fails to pass the examination in a certain board because he has failed on one subject, he should be barred or denied the privilege of reciprocity, especially if that individual has been in practice and has made good. We have reciprocity with the state of New York, and we have a special agreement with the state of Pennsylvania by which we give men who are licensed in Pennsylvania the same privileges that Pennsylvania gives men licensed in Puerto Rico. Pennsylvania makes a special case of every individual, that is to say, it is not obliged to give reciprocity to any of our men just because they solicit it but it studies the case and if it thinks the individual deserves it, it extends that courtesy. We do the same thing. With New York State we have a reciprocal agreement by which it extends reciprocity to all the men who hold licenses of the state of Puerto Rico. If an individual graduated at a time when the requirements were less than at present, New York and Puerto Rico consider five years of practice in the state an equivalent to the requirements which that individual has not met. That is why I think the boards should make an individual case of every one that applies for a license, as they do in Louisiana, because in that way one gives a fairer chance to any one who comes up for licensing.

DR J. N. BAKER, Montgomery, Ala. Recently I checked up on the men who had appeared before our board for the last ten or eleven years. We have not rejected a single man in the last ten years who was a graduate of a grade A medical school which is a requirement of our board so far as examination is concerned. I have the feeling that after a young man has spent so much of his life in equipping himself at a grade A medical school, with one or two years of hospital training, it is not fair for an examining board to make him go over the elementary grounds again. Our licensing boards have served a most valuable purpose. When we had diploma mills we had to protect both the recognized medical profession and the public at large, but now I think we have set up a machine that we can rely on. Reciprocity should be carefully considered by every licensing board. So far as admitting a man to my state is concerned, if he shows good technical training I would rather spend several months investigating his character and moral fiber before he comes into Alabama. I think that is one of the most valuable points to be borne in mind by licensing boards.

DR CROWE. If you will all commence an index of men who have been convicted of crime and whose licenses have been revoked in other states, taking newspaper clippings and the *Federation Bulletin* showing the convictions in the various states, you will be surprised how large a list you will have of men who will approach you for a license, whose licenses were revoked in some other state or who have been convicted of a crime of some kind. I suggest that that method be pursued, and also that you resort to the files of the biographic department of the American Medical Association for further information on every applicant who comes to you for reciprocal endorsement. In Texas we cut the word "reciprocity" out of our statute. We do not reciprocate, and yet we receive men from every state in the Union, regardless of what the other states will do for our licentiates. We take the man on his merits and on his qualifications.

MEDICAL BROADCAST FOR THE WEEK

American Medical Association Health Talks

The American Medical Association broadcasts on Tuesday and Thursday from 9 15 to 9 20 a m. Chicago daylight saving time which is one hour faster than central standard time, over Station WBBM (770 kilocycles or 389.4 meters).

The subjects for the week are as follows:

May 23 Vacations and Typhoid
May 25 Hitch Hikers

There is also a fifteen minute talk sponsored by the Association on Saturday morning from 9 45 to 10 o'clock over Station WBBM.

The subject for the week is as follows:

May 27 Swimming Hazards

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION PUBLIC HEALTH ETC.)

ARKANSAS

Personal—Dr John R. Kitley has been reelected mayor of Mayflower—Dr Frank C. Maguire, Augusta, was recently appointed coroner of Woodruff County—Dr Charles A. Arkebauer, Little Rock, who has been associated with the State Hospital for Nervous Diseases for thirty-two years, has been elected chief of the medical staff, a position recently created to replace that of superintendent—Dr George A. Hays, Pine Bluff has resigned as director of the city and Jefferson County health departments after four years' service.

Society News—The Sebastian (Ark.) and Muskogee County (Okla.) medical societies were addressed at a joint meeting, recently, by Drs. Joel T. Woodburn on childhood tuberculosis, James F. Campbell, epidemiology of ringworm, John H. White, diagnosis and treatment of goiter, and Charles E. White, use of calcium in pregnancy. All the speakers were from Muskogee, Okla.—A recent meeting of the Union County Medical Society was addressed by Drs. John A. Moore and Arley D. Cathey, El Dorado, on influenza with complications and ectopic pregnancy, respectively—Drs. Francis T. H. Doubler and Elmer G. Wakefield, Springfield, Mo., gave a joint paper on "Preoperative and Postoperative Care of Pyloric Obstruction" before the Washington County Medical Society, recently.

CALIFORNIA

Society News—At a meeting of the San Francisco County Medical Society, May 9, Drs. Robert C. Coffey, Portland, Ore., spoke on "Quarantine Principle as Applied to the Treatment of Disease," and Sadie D. Patek, "A Study of the Results of Specific Treatment of Syphilitic Pregnant Women and Their Offspring."—A preview of the installations of habitat groups of African mammals in its museum was a feature of the celebration of the eightieth anniversary of the founding of the California Academy of Sciences in San Francisco, April 4. When completed, these installations will include ten large groups, thirteen intermediate small size groups and one very large waterhole group. All will be artificially illuminated.—A Greek program was presented by the California Medical History Seminar at the Bohemian Club in San Francisco April 21. Dr. Pan S. Codellas discussed the work of Adamantios Koraes (1748-1833).

Bills Enacted—The following bills have become laws: A 317, amending the state narcotic drug act, by (1) requiring practitioners to preserve for not less than two years records of narcotic drugs prescribed, administered or dispensed, (2) providing that proof of the possession by the defendant of a greater amount of narcotic drugs than is accounted for by his records shall be prima facie evidence of guilt, (3) forbidding the possession of a false or fictitious prescription or one that has been altered by any person other than the prescriber, and (4) providing for the forfeiture of vehicles used in the unlawful transportation of narcotic drugs. A 318 amending an act to regulate the sale of poisons, approved March 6 1907, by (1) providing that the registration of any registered pharmacist may be revoked on conviction of violating any of the narcotic provisions of the act, (2) making it "unlawful for any person to open or maintain, to be resorted to by other persons, any place where opium or hemp or loco weed is sold or given away to be smoked on the premises," and for any person to resort to such a place, (3) making it legal for registered nurses to acquire and possess without written orders from licensed physicians, hypodermic syringes and needles, (4) defining "physician" to include licensed osteopaths, (5) prescribing a procedure for forfeiting vehicles used in the unlawful transportation of narcotic drugs, and (6) permitting physicians in good faith to prescribe or furnish narcotic drugs to patients suffering with incurable diseases, ailments or injuries, other than narcotic addiction, and requiring physicians prescribing or furnishing narcotics to habitual users to report that fact by registered mail to the division of narcotic enforcement.

COLORADO

Bill Passed—H 734 has passed the house, proposing to create a state board of osteopathic examiners to exercise all the rights and powers and perform all the duties now vested by law in the state board of medical examiners with respect to the practice of the healing arts by osteopaths.

CONNECTICUT

Bill Enacted—H 570 has been enacted as chapter 139, Laws of 1933 amending the medical practice act by (1) providing that all applicants for licenses, whether by examination or by reciprocity, shall be citizens of the United States or shall have on file written declarations of intention to become citizens, (2) raising from \$15 to \$50 the fee required for issuing licenses by reciprocity (3) exempting from examinations holders of certificates from the National Board of Medical Examiners, although they have not been in active practice for three years and (4) providing that persons, graduates from medical colleges prior to Jan 1, 1919, and persons eligible for examination before that date shall not be required to have a one year college course in chemistry, physics and general biology, as is required of all other applicants

FLORIDA

Bills Introduced—S 212 proposes to authorize the state board of health to license persons to practice midwifery, and to promulgate such rules and regulations as it may deem necessary for regulating the practice of midwifery S 373 and H 686 propose to require the annual registration of pharmacies with the state board of health, and to authorize the state board of health to appoint one or more registered pharmacists to act as inspectors to aid it in enforcing the pharmacy practice act. H 685, to amend the pharmacy practice act, proposes to raise the annual registration fee required of registered pharmacists from \$1 to \$5 H 769 proposes that all members of the state boards of medical examiners osteopathic examiners, chiropractic examiners and naturopathic examiners shall receive \$25 for each day they are actually engaged in the discharge of their official duties and 3 cents for each mile necessarily traveled in going to and from meetings of their boards H 774 proposes to permit all licensed practitioners of the healing art to practice within the confines of all hospitals maintained wholly or partly by public funds and to treat their patients therein in accordance with the method of their several schools of healing H 771 proposes to require physicians, osteopaths chiropractors and naturopaths to pay an annual license fee of \$5 to the boards which licensed them Ten per cent of the fees so collected is to be remitted to the state treasurer and the remainder is to be retained by the several boards H 768 proposes that a person required by statute to be examined and to have a certificate showing the state of his health may be examined by and obtain such a certificate from any practitioner of the healing art H 773 proposes to authorize the boards of medical examiners osteopathic examiners, chiropractic examiners and naturopathic examiners to grant licenses without examinations to licentiates of like boards of other states whose requirements are equal to the requirements of Florida H 772 proposes to require all applicants for licenses to marry to present certificates from licensed practitioners of the healing art that both parties to the proposed marriages are in good physical condition and are free from communicable diseases H 770 proposes to require the governor to appoint one doctor of medicine, one osteopath, one chiropractor and one naturopath to serve on the board of governors or board of trustees of every hospital and other institution maintained wholly or partly by the state funds

ILLINOIS

Bills Introduced—H 784 and 785 propose to create a board of chiropractic examiners and to regulate the practice of chiropractic. Chiropractic is defined to be the science of palpating and adjusting the articulations of the human spinal column without the use of drugs or surgery Applicants for such a license must be high school graduates and have graduated from schools of chiropractic approved by the department of registration and education, after completing courses for three school years of not less than six months' duration each However, persons who on the 31st of December, 1933, are students in schools of chiropractic may be licensed even though they do not have high school educations and their chiropractic schools are not approved by the department H 808 proposes extensive amendments to the Illinois dental practice act It exempts from the operation of the act 'the rendering of dental relief in emergency cases in the practice of his profession by a physician or surgeon, licensed as such and registered under the laws of this state, unless he undertakes to reproduce or reproduces lost parts of the human teeth in the mouth or to restore or replace in the human mouth lost or missing teeth' H 842 and H 843 propose to create a board of examiners for 'the medical practitioners who practice osteopathy' and to regulate the practice of osteopathy The board is to be authorized to issue two kinds of licenses (1) licenses to practice osteopathy in all its branches (according to the teaching of the osteopathic

school of practice) and (2) licenses to practice osteopathy in all its branches, except major surgery The holders of both kinds of licenses are to be permitted to make and sign birth and death certificates and to practice in hospitals supported in whole or in part by public taxation

Chicago

Miller Finally Pays His Fine—With the payment of a \$2000 fine to the clerk of the criminal court April 24 the case of William Henry Harrison Miller, former director of the state department of registration and education as related to diploma mill activities apparently was brought to a close Miller's first flagrant violation of the law was disclosed in April, 1922 when the Cook County grand jury charged him and three others with trafficking in state licenses to practice in various professions He had been appointed director of the state department in January, 1921 It was revealed during the investigations that the questions to the state board examinations were being sold to prospective applicants Following an investigation by the state's attorney and a committee appointed by the governor, Miller was indicted by the grand jury for conspiracy and was found guilty Jan 28, 1923 He paid a fine of \$1000 in open court, Jan 30 1923 Miller's dismissal by Governor Small had occurred in August 1922 following his refusal to resign after the medical board had recommended his removal A M Shelton, Crystal Lake succeeded him as director Hearings were begun April 13 1923 to revoke all licenses illegally issued under Miller's administration In the interim however several states had suspended reciprocal relations with Illinois on account of the investigation but these were restored following the board's reorganization in the latter part of 1922 Again on Dec 10 1929 Miller was found guilty of conspiracy to sell medical and dental licenses to persons not qualified to practice This trial was the result of an investigation carried on by a new administration into the charges of illegal traffic in licenses The chief state witness was the late Dr Robert Adcox St Louis who was involved in the Missouri diploma mill expose in 1923 He, it was claimed conspired with Miller in 1928 These new charges were preferred against Miller following his indictment with several others on the charge of operating a 'ring' to sell medical and dental licenses This ring had in its possession special license plates During the investigation an attempt was made to lose these plates in the drainage canal Two forged seals were recovered by divers from Lake Michigan near the Navy Pier The sentence imposed in this instance was seven months and one day in jail and a maximum fine of \$2000 Miller was denied a new trial Jan 5 1930 but he was at liberty without bond until Jan 22 1932 when he was arrested in Champaign He had failed to post a bond for his appeal and officials neglected to commit him to jail pending its schedule Miller served the seven months sentence but was detained in jail on its completion because of failure to pay the \$2000 fine In his petition for release Miller stated that he was penniless having transferred all his property to his wife in Champaign In a previous hearing however the judge had indicated that the transfer was fraudulent In November, 1932 he was released from the county jail on a \$3500 bond Under a decision given by the Illinois Supreme Court April 22 Miller was ordered to pay the \$2000 fine or serve an indefinite time in the county jail He paid the fine

IOWA

Lectures on the Heart.—The Dickinson County Medical Society at its meeting February 23, inaugurated a series of monthly lectures on the heart to continue through July Physicians participating in the series and their subjects are as follows

Charles S Shultz Spirit Lake Anatomy and Physiology of the Heart.
Clyde C Nicholson Spirit Lake Acute Pericarditis
Donald F Rodawig Spirit Lake Myocardial Disturbances
Peter C Grimm Spirit Lake Endocarditis
Edward J Johnson Milford Arrhythmias
Ruth F Wolcott, Spirit Lake Auricular Fibrillation
Ferdinand J Smith Milford Arteriosclerosis and Hypertension
Cassius M Coldren Milford Cardiovascular Renal Disease
Quintus C Fuller Milford Coronary Thrombosis
Earl R Leonard Lake Park Aortic Valvular Lesions
Alfred H Schooley Terrell Mitral Valvular Lesions
William E Bullock, Lake Park Treatment of Decompensation.
Ferdinand J E Smith Milford Essential Hypertension

MARYLAND

Dr Bard Appointed Professor of Physiology at Johns Hopkins—Philip Bard PhD assistant professor of physiology, Harvard University Medical School has been appointed professor of physiology at Johns Hopkins University School of Medicine effective September 1 This professorship has been vacant since the resignation in 1931 of Dr William H Howell

who had held the position since 1893. Dr. Bard was connected with Harvard from 1925 to 1928 and with Princeton University from 1928 to 1931 as assistant professor of biology. In the latter year he rejoined the staff at Harvard as assistant professor of physiology.

Review Course for Physicians—The division of medical extension of the University of Maryland will conduct its tenth annual review course for physicians, June 5-23. This will be a single, intensive general course, designed to give to the physician in general practice the opportunity of studying those methods of diagnosis and treatment in current use in the University Clinics. This year the course will be limited to twenty men. A matriculation fee of \$25 will be charged residents of the state, while registrants from out of the state will be charged \$50. The program will consist of lectures, ward rounds, clinics and dispensary clinics. Afternoon periods will be devoted to laboratory methods of diagnosis. Further information may be obtained from the dean of the University of Maryland School of Medicine, Baltimore.

MASSACHUSETTS

Dr. Cushing Receives Bigelow Medal—Dr. Harvey Cushing, until his resignation last year Moseley professor of surgery, Harvard University Medical School, Boston, was presented with the Bigelow Medal by the Boston Surgical Society, May 3. The late Dr. William Sturgis Bigelow, in 1915, gave the society a sum of money with the stipulation that the interest from the funds should from time to time be devoted to the presentation of a medal to one chosen for his 'contributions to the advancement of surgery.' The medal was a memorial to his father, the late Dr. Henry Jacob Bigelow. In the eighteen years since its establishment, the medal has been awarded only six times.

- 1921 Dr. William J. Mayo, Rochester, Minn.
- 1922 Dr. William W. Keen, Philadelphia
- 1926 Dr. Rudolph Matas, New Orleans
- 1928 Dr. Chevalier Jackson, Philadelphia
- 1931 Prof. George Grey Turner, Newcastle upon Tyne, England
- 1932 Dr. John M. T. Finney, Baltimore

Dr. Cushing presented a paper at this meeting on "Homo Chirurgicus."

Health Education Meeting—The eighth annual session of the New England Health Education Association will be held at the Massachusetts Institute of Technology, Boston, June 2-3. Samuel C. Prescott, head of the department of biology and public health of the institute, will give the address of welcome.

"Nutrition and the School Child" will be discussed by Miss Gertrude Spitz, chief of food clinic, Beth Israel Hospital, Boston. "School Problems in Mental Health," James Mace Andrews, Ph.D., Newtonville. "Physical Education and the School Health Program," Mr. Richard Schmojer, director of health and physical education public schools of Lynn, and "Administration of the School Health Program," Clair E. Turner, Dr. P.H., professor of biology and public health at the institute. Dr. Haven Emerson, professor of public health administration at Columbia University College of Physicians and Surgeons, New York, will speak on "Medical Facts and Popular Fallacies as to the Effects of Alcohol on Man" and Dr. Frankwood E. Williams, New York, "Youth, the School and the Present-Day World."

State Medical Meeting in Boston, June 5-7—The one hundred and fifty-second annual meeting of the Massachusetts Medical Society will be held in Boston, June 5-7, with headquarters at the Hotel Statler and under the presidency of Dr. Halbert G. Stetson, Greenfield. Out of state speakers on the program will include the following:

- Dr. Frederick C. Holden, New York, Pelvic Inflammation: Course and Treatment—Elliott Heat Apparatus
- Dr. James Burns Amberson, Jr., New York, Changing Aspect of Tuberculosis Treatment
- Frank A. Hartman, Ph.D., Buffalo, Certain Functions of the Adrenal Cortex
- Dr. William H. Schmidt, Philadelphia, Fever Therapy and Other Recent Developments in Physical Therapy
- Dr. Eugene P. Pendergrass, Philadelphia, Pneumonoconiosis
- Dr. John J. Moorhead, New York, Relation of Trauma in Hernia

Other speakers will include the following physicians:

- Foster S. Kellogg, Boston, Placenta Praevia
- Carmi R. Alden, Newton, Center and Boston, Use of Pituitrin in Obstetrics
- Alton S. Pope, Newton, Pulmonary Tuberculosis in Adolescence with Special Reference to Frequency, Diagnosis and Prognosis
- George W. Holmes, Boston, Conditions in Which the Roentgen Examination May Lead to an Erroneous Diagnosis of Pulmonary Tuberculosis
- Joseph C. Aub, Boston, Progress in the Study of Internal Secretions
- Henry S. Finkel, Boston, Present Status of Our Knowledge of the Ovarian Hormones
- Fuller Albright, Boston, Hyperparathyroidism: Its Diagnosis and Exclusion
- Tracy J. Putnam, Brookline, Present Status of Disease of the Hypophysis

- George L. Stivers, Worcester, Use of Surgical Diathermy (or Endothermy) in Separating Pleural Adhesions in Cases of Pulmonary Tuberculosis
- Richard H. Miller, Boston, Umbilical Hernia
- Henry C. Marble, Newton and Boston, Problem of Recurrent Hernias
- Richard B. Cattell, Boston, Diseases of the Thyroid Gland in Children
- Edwin T. Wyman, Boston, Vitamin D Milk
- Paul W. Emerson, Boston, Feeding of Human Milk Preserved by Freezing
- Cleophas P. Bonin, D.M.D., Boston, What the Pediatrician Can Do for Dental Cripples

Dr. Elhott C. Cutler, Moseley professor of surgery, Harvard University Medical School, will deliver the Shattuck Lecture on "The Origins of Thoracic Surgery." Dr. Channing Frothingham, Boston, will present the annual discourse on "The Trend of Medicine in the Twentieth Century." Mr. James H. Holland, of the Liberty Mutual Insurance Company, Boston, has been invited to speak on "Hernia from the Compensation Insurance Standpoint."

MICHIGAN

Bills Introduced—H. 579 to amend the chiroprody practice act, proposes, in effect, to permit licensed chiroprodists to treat ailments of the human leg and foot medically, surgically, mechanically or by physiotherapy. The bill proposes too, to permit such licentiates to use the title "Dr." if the word "Chiroprodist" follows their names. S. 204 proposes to permit licensed physicians to prescribe such amounts of intoxicating liquors as they deem necessary to supply the bona fide medical needs of their patients. S. 195 proposes that the law prohibiting employment of males under the age of 18 years and females for a period longer than fifty-four hours in any week or ten hours in any one day shall not apply to the employment of student and graduate nurses in privately owned hospitals.

MINNESOTA

Society News—The Minnesota Hospital Association will hold its annual convention in Minneapolis, May 25-26. Speakers will include Drs. George F. Stephens, superintendent, Winnipeg General Hospital; Winnipeg, Manit.; Bert W. Caldwell, executive secretary, American Hospital Association, Chicago; Malcolm T. MacEachern, director, hospital activities, American College of Surgeons, Charles H. Mayo, Rochester, and Clarence Rufus Rorem, Ph.D., associate for medical services, Julius Rosenwald Fund, Chicago. At a meeting of the Minnesota Academy of Medicine, May 10, Drs. Edwin L. Gardner, Minneapolis, spoke on "Calcium Deficiency Associated with Functional Gastrointestinal Disturbances in Adults" and Henry E. Michelson, Minneapolis, "Tuberculodermas of the Face."

NEW HAMPSHIRE

Bills Introduced—S. 34 proposes that the board of medical examiners, the board of examiners of embalmers, board of examiners in chiroprody, board of chiropractic examiners, board of registration in optometry, the state dental board and the commission of pharmacy and practical chemistry be attached to the state board of health for the purposes of general administration. It is to be the duty of the state board of health to provide facilities for the meetings of the boards named and for the custody and care of their records and to exercise such general supervision over their operations as will enable it to satisfy itself that such boards are properly performing all the duties imposed on them by law. S. 37 proposes to make the reasonably permanent insanity of either spouse a cause for divorce.

NEW YORK

Personal—Frank A. Hartman, Ph.D., professor of physiology, University of Buffalo, was recently awarded the Schoellkopf Medal for 1933 in recognition of his work on cortin. The medal is bestowed by the western New York section of the American Chemical Society. Dr. Clara H. Pierce, Syracuse, was elected president of the Women's Medical Society of New York State at the annual meeting in New York, April 3. A painting by Dr. Konrad E. Birkhaug, now an investigator in the Institut Pasteur in Paris, has been accepted for Le Salon de 1933, the annual exhibit of art in Paris, and a series of four large aquarelles for the annual exhibit of students work made by the Societe Nationale des Beaux-Arts.

Nassau County Tumor Clinic—The Nassau County Cancer Committee, a branch of the American Society for the Control of Cancer, has organized a temporary clinic for diagnosis and treatment of tumors at the Nassau County Tuberculosis Sanatorium, Farmingdale. Citizens of Nassau County contributed funds for radium and the board of managers of the proposed new Meadowbrook Hospital made available a high voltage therapy x-ray machine. It is expected that all the clinic facilities will be transferred to Meadowbrook Hospital when it is completed. The committee has organized a

rotating service of attending physicians, with the assistance of the Medical Society of the County of Nassau and the medical boards of the three larger hospitals of the county. This clinic was established, the committee announced, to provide diagnosis and treatment for persons unable to meet the costs of the service through private channels. In addition, roentgen therapy is available for those able to pay, since the clinic is the only place in the county where a tumor patient confined to bed may receive this treatment. It also aims to supply graduate education to the physicians of the county. A charge of \$3 a day is made for all patients, as there is no appropriation to cover the expenses of the clinic. Those who are unable to meet the expense themselves may arrange for care through the welfare authorities. All patients must be referred through private physicians; the county medical society will assist those who have no family physician in selecting one. Patients will be given care only with the advice and consent of the physician who stands in the position of family physician.

New York City

Course on Heart Disease—Columbia University's extension division announces that an intensive four weeks' course on diseases of the heart and circulation will be given at Mount Sinai Hospital, June 5 to July 1. A limited amount of time will be devoted to lectures and an attempt will be made to conduct the course so as to recreate for the student conditions of actual practice. The fee for the course will be \$100. Instructors will be Drs. Murray H. Bass, Ernst P. Boas, Arthur M. Fishberg, Louis Gross, Maurice A. Kugel, Hubert M. Mann, Arthur M. Master, Hermann Mond, Bernard S. Oppenheimer, Irving R. Roth and Marcy L. Sussman.

The Prevention of Asphyxial Death—The newly organized Society for the Prevention of Asphyxial Death has called a conference of physicians, hospital executives, health commissioners and insurance and utility company officials of New York state to meet at the New York Academy of Medicine May 24, under the auspices of the academy's committee on public relation. Addresses will be delivered by the following:

- Dr. Shirley W. Wynne, New York City health commissioner, vital statistics relating to asphyxia.
- Dr. Harrison S. Martland, Newark, N. J. medical examiners' findings in asphyxial cases.
- Dr. Daniel J. Donovan, chief surgeon, New York City police department, first aid and resuscitation methods.
- Albert W. Whitney, associate general manager, National Bureau of Casualty and Surety Underwriters, economic aspects of asphyxial mortality.
- Dr. Chevalier Jackson, Philadelphia, fundamentals of laryngoscopy as applied in resuscitation.
- Landell Henderson, Ph.D., New Haven, Conn., use of oxygen and carbon dioxide in resuscitation.
- Dr. Edmund B. Piper, Philadelphia, practical application of laryngoscopy and gas therapy.
- Dr. Pol N. Coryllos, New York, negative pressure cabinet in treatment of asphyxia.
- Dr. John F. McCrath, New York, ways and means of applying the improved resuscitation principles to medical and hospital practice.

A preliminary report issued by the directors of the society calls attention to the fact that asphyxial death is an important public health problem. More than 50,000 deaths from asphyxia occur in the United States every year, approximately 2,800 in New York City alone. The death rate from this cause in New York is said to be twice that from automobile accidents. The report lists fifteen causes of acute asphyxia and death, including submersion, poisoning from illuminating gas, carbon monoxide and drugs, electrical shock, acute alcoholism, pulmonary diseases, suffocation from strangulation, poliomyelitis and asphyxia of the still-born.

NORTH DAKOTA

State Medical Meeting at Valley City, May 31-June 2—The annual meeting of the North Dakota State Medical Association will be held at Valley City, May 31-June 2, under the presidency of Dr. Paul H. Burton, Fargo. The tentative program includes the following physicians as speakers:

- Frederick C. Rodda, Minneapolis, Intussusception.
- Albert M. Brandt, Bismarck, Diagnosis and Treatment of Primary Uterine Bleeding.
- Leonard W. Larson, Bismarck, Legislative Matters.
- Frank I. Darrow, Fargo, Diabetes Mellitus.
- John D. Carr, Jamestown, Promotion of Preventive Mental Medicine.
- James F. Hanna, Fargo, Treatment of Persistent R. O. P. Position.
- Alano E. Pierce, Minot, Coronary Thrombosis.
- John deJ. Pemberton, Rochester, Minn., Carcinoma of the Rectum and Rectosigmoid.
- Reuben H. Waldschmidt, Bismarck, Treatment of Fractures of the Spine.
- Robert W. Allen, Bismarck, A Plan for Tuberculosis Control in North Dakota.
- John D. Graham, Devils Lake, Rectal Anesthesia in Obstetrics.

Clinics will be conducted by Drs. Pemberton and Rodda, and Melvin S. Henderson, Rochester. The annual dinner will be addressed by Dr. Frank L. Rector, Evanston, Ill., on "Cancer

Control in North Dakota", L. Benshoof, editor the *Detroit Record*, Detroit Lakes, Minn., "Medical Publicity," and Richard E. Scammon, Ph.D., Minneapolis, "Guild Medicine."

OKLAHOMA

Bill Enacted—H. 43 has become a law, prohibiting the possession and distribution of veronal, barbitol, luminal, chloral hydrate, bromidia or somnos except on the prescription of a licensed practitioner of medicine, osteopathy, dentistry or veterinary medicine.

PENNSYLVANIA

Personal—Dr. Harry W. Mitchell has resigned as superintendent of Warren State Hospital, Warren, after twenty-one years' service. Dr. Mitchell is reported to be critically ill. Dr. Ira A. Darling succeeds him at the hospital.—Dr. Wilhelm L. Scott has recently resigned as resident physician at Rossmore Sanatorium, Lancaster. She was succeeded by Dr. Lloyd S. Hutchison.

Philadelphia

Society News—The thirtieth Mary Scott Newbold Lecture of the College of Physicians of Philadelphia was delivered May 3, by Dr. Ronald T. Grant, University College Hospital Medical School, London, on "Prognosis of Valvular Disease of the Heart." Dr. Grant gave a second lecture on the subject, May 5.—Dr. Norman S. Rothschild, among others, addressed the Philadelphia Academy of Surgery, May 1, on "Repair of Large Incisional Hernia by Flaps of Anterior Sheath of Rectus."—Dr. Abraham M. Ornstein addressed the Philadelphia Medical Examiners' Association May 1, on "Medico-legal Problems."—Drs. Albert C. Buckley and Mitchell P. Warmuth were speakers at a meeting of the Philadelphia Clinical Association, May 2, on "Psychiatric Problems in General Medicine and the Specialties" and "Acute Hemorrhagic Pancreatitis," respectively.—Drs. Juan H. Font and John L. Quinn, among others, addressed the Philadelphia Laryngological Society, May 2, on "Syphilis of the Middle Ear" and "Diagnosis and Treatment of Laryngeal Tuberculosis," respectively.

VIRGINIA

Promotions at Medical College—At the midwinter meeting of the board of visitors of the Medical College of Virginia, Richmond, the following promotions were announced:

- Dr. Wyndham B. Blanton to professor of medicine.
- Dr. William R. Bond to professor of physiology and associate professor of pharmacology.
- Dr. Robert H. Courtney to associate professor of ophthalmology.
- Dr. Harvey B. Haag, professor of pharmacology and associate professor of physiology.
- Dr. Daniel D. Talley, Jr., to professor of roentgenology, succeeding the late Dr. Alfred L. Gray.
- Harry Lyons, D.D.S., professor of periodontia and oral pathology.

A portrait of Dr. Richard L. Bohannon, first professor of obstetrics and diseases of women and one of the founders of the Medical College of Virginia, has been presented to the college by his descendants, for the Founders' Room in the new library.

Activities of Richmond Academy—The Richmond Academy of Medicine has begun publication of a quarterly bulletin, the first issue dated March. The new bulletin is a part of a general reorganization undertaken by the academy since its new building was opened in September, 1932. The Richmond Ophthalmological, Rhinological and Otological Society recently voted to become the eye, ear, nose and throat section of the academy, and similarly the Richmond Pediatric Society is now the pediatric section. Other sections will be organized according to the bulletin. The academy has also inaugurated monthly clinical meetings to be in charge of Richmond hospitals in rotation. Drs. William Gerry Morgan and Wallace M. Yater, Washington, D. C., addressed the academy April 11 on "Hepatosplenography" and Dr. Frederick M. Hodges, "Therapy of Keloids." Drs. Isaac A. Bigger and Joseph Bear, spoke, May 9, on "Treatment of Superficial Burns" and "Treatment of Eclampsia," respectively.

WISCONSIN

Society News—The Milwaukee Pathologists Society was recently organized with Drs. Edward L. Tharinger as president and Marcos Fernan-Nunez as secretary.—Dr. Chester C. Schneider addressed the Milwaukee Pediatric Society, April 19, on "Fractures in Children."—Drs. W. F. Lorenz, Madison, and James P. Simonds, Chicago, addressed the Milwaukee County Medical Society, Milwaukee, April 14, on "Neurosyphilis" and "Newer Problems in Immunity to Disease," respectively.—Dr. Walter M. Simpson, Dayton, Ohio, addressed the Milwaukee Academy of Medicine, April 18, on

undulant fever Speakers before the academy May 16 were Drs Lester M Wieder on 'Rhinoscleroma', James C Sargent, 'Careful Diagnosis and Conservative Management of Urinary Stones,' and J Edwin Habbe, 'Roentgen Findings in Splenomegaly'

Radiologic Meeting—Dr Arthur U Desjardins Rochester, Minn, was the guest speaker at the annual meeting of the section on radiology of the Wisconsin State Medical Society at Fond du Lac May 19-20 Dr Desjardins presented two addresses on 'The Action of Roentgen Therapy on Tuberculous Processes and Roentgen Therapy as a Means of Treating a Variety of Tumors' the latter at a joint session with the Fond du Lac County Medical Society Among Wisconsin physicians who presented papers were

Ernst A Pohle Madison Experience with the Protracted Fractional Dose Method
Barton W Johnson Fond du Lac Early Diagnosis of Obstruction of the Ileum
Theodore Sokow Kenosha Chondromatosis
Harry R Foerster Milwaukee Radiodermatitis
Harry B Podlasky Milwaukee Pathogenesis of Gastric Ulcer

GENERAL

Annual Session of American Heart Association—Under the chairmanship of Dr Walter W Hamburger Chicago the American Heart Association will hold its ninth annual session in Milwaukee, June 13, at the Knickerbocker Hotel The program for the two sessions follows

Dr Currier McEwen New York, Cytologic Studies of Granulomata and Exudates from Patients with Rheumatic Fever
Dr Edwin P Jordan Chicago Importance of Allergy in Rheumatism
Dr Thomas Duckett Jones and Josephine McBroom AB Boston Studies on the Etiology of Rheumatic Fever
Dr Katharine M Howell and Eleanor P Burton BA Chicago Dissection of Streptococci Obtained from Rheumatic Fever
Drs Otto Saphir and Simon A Wile, Chicago, Rheumatic Manifestations in Subacute Bacterial Endocarditis in Children
Dr Samuel A Levine Boston A Clinical Conception of Rheumatic Heart Disease
Drs Charles S Stone and Harold Feil Cleveland Clinical and Pathological Study of One Hundred Cases of Mitral Stenosis
Drs Clarence L de la Chappelle Irving Graef and Antonio Rottino, New York Relationship of Auricular Fibrillation to the Grade of Mitral Stenosis and the Presence of Active Rheumatic Infection
Drs Bernard S Oppenheimer and Sidney P Schwartz New York Paroxysmal Pulmonary Hemorrhages The Syndrome in Young Adults with Mitral Stenosis
Drs Soma Weiss and David Davis Boston Embolic Manifestations in Rheumatic Heart Disease
Dr John P Anderson Cleveland Electrocardiographic Findings in Experimental Pulmonary Embolism
Drs Arthur M Master and Harry L Jaffe, New York The Heart in Rheumatic Fever and Rheumatoid (Infectious) Arthritis
Dr Ann P Purdy, San Francisco Lesions of the Kidney Associated with Rheumatic Heart Disease
Drs William Chester and Sidney P Schwartz New York Skin Lesions in Rheumatic Fever
Dr Edward Sterling, Nichol Miami Fla. Rheumatic Heart Disease in Florida
Dr Hugh McCulloch St Louis Convalescent Care of Cardiac Children
Drs Thomas Duckett Jones and Edward F Bland Boston The Course and Prognosis of Rheumatic Fever and Chorea

Medical Bills in Congress—*Bills Introduced* S J Res 45 introduced by Senator Copeland, New York, and H J Res 158, introduced by Representative Eaton New Jersey propose to authorize an appropriation of \$10,000 for the expenses of participation by the United States in the Seventh International Congress of Military Medicine and Pharmacy S 1292, introduced by Senator Tydings Maryland, proposes to provide medical services after retirement on annuity to employees of the United States disabled by injuries sustained in the performance of their duties S 1515 introduced by Senator Copeland, New York, proposes to grant permits for the importation or manufacture for nonbeverage purposes of spirituous liquors of particular kind or quality where the supply in the United States is insufficient to meet the current need therefor H R 4346 introduced by Representative Kvale Minnesota, proposes to authorize an appropriation of \$250,000 for the extension and betterment of the state sanatorium at Ah Gwah Chung Minn H R 4885 introduced by request by Representative McKeown Oklahoma, proposes to establish a laboratory for the study of the criminal dependent and defective classes H R 5308 introduced by Representative Mead New York proposes to make available hospitalization and medical treatment in hospitals and relief stations of the United States Public Health Service to (a) officers of documented vessels who are holders of unexpired licenses of the United States Steamboat Inspection Service (b) seamen who have served forty days or more on a documented vessel during the year preceding application for hospitalization or treatment and (c) seamen whose wages were diminished by reason of contributions made to the fund for the relief of sick and disabled seamen H R 5326 introduced by Representative Granfield Massachusetts sets proposes to authorize an appropriation not to exceed \$500,000 to erect an addition to the Veterans Administration hospital at Northampton, Mass

American Association for the Advancement of Science—Section N—At the summer session of the American Association for the Advancement of Science in Chicago June 19-23 section N (the medical sciences) will sponsor four symposiums and a public meeting Headquarters will be at the Knickerbocker Hotel Monday morning June 19, the section will join with section C (chemistry) at Thorne Hall Northwestern University for a symposium on colloid chemistry as related to biologic problems with the following speakers

Edwin J Cohn Ph.D. Harvard Medical School Boston Electrostatic Forces in Systems Containing Biological Components
Prof Theodor Svedberg Uppsala University Sweden Sedimentation Constants and Molecular Weights of the Respiratory Proteins
Prof Filippo Bottazzi Naples Italy Physicochemical Properties of Concentrated Blood Serum

Tuesday morning June 20 section N will combine with section F (zoology) in a symposium with the following speakers

Prof Archibald V Hill London England Physical and Chemical Changes in Nerve During Activity
Wallace O Fenn Ph.D. Rochester Minn Nerve Respiration
Dr Ralph W Gerard Chicago Chemical Activity of Nerve
Dr Herbert S Gasser New York, Electric Phenomena in Nerve

Wednesday morning a symposium on pathologic physiology will be held at Northwestern University, in which the following will participate

Dr William H Park New York BCG Vaccination
Dr Charles H Best Toronto Fatty Changes in the Liver of Normal and Diabetic Animals
Dr Arthur L Tatum Madison Wis Morphine Addiction and Morphine Tolerance
Dr Maurice B Strauss Boston Etiology of Pernicious Anemia and the Related Macrocytic Anemias

Thursday morning June 22 a surgical-endocrinologic symposium will be presented at Northwestern by the following

Dr George W Crile Cleveland A Century of Progress in Surgery
Anesthesia Antisepsis and Asepsis Shock and Careful Handling of Tissues
Dr Max Ballin Detroit Clinical Recognition and Surgical Treatment of Parathyroidism
Dr Percival Bailey Chicago Surgical Control of Hypophyseal Disorders
Dr John deJ Pemberton Rochester Minn Recent Developments in the Clinical Recognition and Surgical Management of Hyperfunction of the Thyroid Gland
Dr Everts A Graham St Louis Clinical Recognition and Surgical Management of Hypoglycemia Produced by Tumors of the Islets of Langerhans

It is expected that Madame Marie Curie Paris, co-discoverer of radium will address some of these meetings

A public meeting celebrating a century of progress in medicine will be held Tuesday evening June 20, in Thorne Hall The program arranged is as follows

Dr Morris Fishbein Chicago editor THE JOURNAL Frontiers of Medicine
Dr Paul Dudley White Boston Heart Disease
Dr Max Cutler Chicago The Conquest of Cancer

Changes in Status of Licensure—The California State Board of Medical Examiners has taken action on the licenses of the following physicians in the manner and on the date indicated

William H McLeod Kansas City Mo license revoked March 7 for his conviction of violation of the Harrison narcotic act
George H Bland Fresno license restored March 7 placed on five years probation without narcotic privileges or possession also without possession of any of the derivatives of barbituric acid License had been revoked Feb 2 1932
Woodward B Mayo Los Angeles license restored February 27 and placed on five years probation. License revoked Oct 20 1931
Francis M Collier Montrose placed on probation for five years without narcotic possession or privileges March 7
Leighton R Cornman San Diego license restored February 27 and placed on probation for five years License suspended Oct 19 1932
Theodore H Niemann Los Angeles license restored March 7, and placed on five years probation without narcotic privileges License revoked July 14 1932
Archibald A Atkinson, Sacramento license restored February 27 and placed on five years' probation without narcotic privileges License revoked Oct 22 1930
Charles Bee Alexander Alhambra license restored February 27 and placed on probation for three years without any instructions as to narcotics alcohol etc License revoked July 12 1932
Charles J Dean Portland Ore, license revoked March 7 because of his conviction in Oregon of violation of bankruptcy laws
Samuel J Hindman Los Angeles license revoked March 1 for narcotic derelictions
Charles M Stewart Los Angeles license revoked March 1 for violation of narcotic laws
Simon R Zachariah San Francisco license revoked March 1 for narcotic violation

The Colorado State Board of Medical Examiners revoked the licenses of the following physicians at its meeting, April 4, for the reasons indicated

Charles Mortimer Stewart Los Angeles for violation of the Harrison narcotic law
David Gordon Minneapolis for violation of the Harrison narcotic law
William I Varnum Minneapolis for unprofessional and dishonorable conduct This license was restored May 6

The Illinois State Department of Registration and Education, Springfield, recently reported the following action

William B. Carolus Sterling license revoked March 17 and Burget Runnels Milledgeville license revoked April 5 on the ground of false claims made by them in advertising matter as to their skill and the efficacy of their medicine for the treatment of specified diseases.

Joseph M. Blakemore Chicago license revoked March 8 for professional connection with an unlicensed person

Dr. Thomas J. Ney Chicago, license revoked January 6 on the ground of his conviction of manslaughter

Dr. Maurice J. Rablins Chicago license restored to good standing Dec. 20, 1932, it had been suspended April 13

Dr. Henry Jules Milestone Chicago license suspended Dec. 16, 1932 for gross malpractice, use of narcotics and making false statements

The Board of Regents of the University of the State of New York reported the following revocation

Dr. William A. Robison Medina, N. Y. license revoked February 16 on the grounds of having committed an abortion and of fraud and deceit in the practice of medicine

The State Board of Medical Education and Licensure of Pennsylvania reported the following

Dr. William H. Kelsea East Brady, Pa. license revoked March 31 because of his conviction in Clarion County courts of having performed an illegal operation

FOREIGN

Jewish Physicians in Germany—The *Münchener medizinische Wochenschrift* for April 28 makes the following notations relative to the status of Jewish physicians under the Hitler regime

Regarding the numerous measures against Jewish physicians in the various states of Germany, no further details are noted since it is the aim of the federal government, in its crusade against the invasion of foreigners into German medical practice [of 6,000 Berlin physicians, 4,500 are reported to be Jews] to prepare a suitable legal foundation and thus to reduce as far as possible the severity against the Jews who have ingratiated themselves to their country. A decree of this type—which will nullify many local regulations—is the decree of April 23 of the national minister of labor concerning the admittance and continuance of occupation of physicians employed by sickness insurance companies. It is made public in the newspapers *Reichsanzeiger* and *Reichsgesetzblatt* [organs for publication of federal laws]. The decree excludes all non-Aryans from future admittance to sickness insurance practice. Also physicians who have been active in the communist party will not be admitted. Non-Aryan physicians, as well as communist physicians, already admitted to sickness insurance practice must be dismissed. According to the law of rehabilitation of professional officials, exceptions are made of non-Aryan doctors who during the World War either fought at the front or were physicians at the front or at military contagious disease hospitals, or whose fathers or sons died in the war. These exceptions do not include physicians who were communists. Physicians admitted to practice before August, 1914, may be retained so far as they were not communists. Thus, the law has been changed by these new specifications. The elimination of already admitted physicians takes force on July 1, 1933, first by means of the associations of insurance physicians; however, the physicians concerned may appeal within two weeks to the federal ministry of labor, which renders the final decision. The appeal is submitted to the executive committee of the association of the physicians of Germany, which forwards it together with an expert opinion to the minister of labor. The physician is not permitted to decline the continuation of his activity on the grounds that his admission will terminate by the new regulation. The application for admission has to be accompanied by (a) certificate of birth and certificates which indicate that the applicant as well as his parents and grandparents, are not full blooded Jews. (b) Non-Aryan physicians who have a right to be admitted must bring proof that their fathers or sons have died in the World War or that they have themselves participated in the World War. In this connection proof has to be brought regarding their military or medical activity at the front or in the military hospitals. In addition to this a certificate of approbation and certificates indicating the former practical, clinical and other medical activities are to be included. The final decision in matters of admission is rendered by the arbitration office of the superior insurance office which has the physicians' register.

'Reports are on hand from Bulgaria, Belgium, Holland, Sweden, Egypt, Czechoslovakia and Rumania that all the Jewish doctors of those respective countries have united in a common boycott against German chemical preparations.'

Prof. Dr. Israel was granted a leave of absence from the Bier clinic in Berlin.

April 22, 1933

The London County Council and the Consultants and Specialists

The controversy with the London County Council in connection with the employment of consultants and specialists has entered a new phase. At a meeting at the British Medical Association house of consultants and specialists, it was resolved to ask the council of the association to take further action on behalf of the consultants in view of an offer of the Voluntary Hospitals Committee to act as mediator, and not to proceed now with the plan of withdrawal. The council considered the matter. The chief complaint of the consultants is that they were not consulted as to the details of the new scheme. The chairman of the council of the association complained of the attitude of Sir Frederick Menzies, chief medical officer of the London County Council who described Dr. Anderson, medical secretary of the association, as fomenting "a strike campaign." Dr. Anderson was only acting on instructions from the association to establish its policy. It was claimed that in dealing with professional appointments to public hospitals the responsible authority should give the profession the opportunity of stating its views on any scheme of organization for such service. Lord Dawson, president of the Royal College of Physicians said that the position was critical. Two years ago the London County Council undertook the stupendous task of converting 100,000 beds previously run on infirmary lines, into the status of hospital beds. An academic atmosphere had been gradually introduced into these municipal hospitals. Physicians and surgeons accustomed to teach had taken part in the work and its standard had been raised. The linkage had been brought about by free consultation between the chief medical officer of the county council and the deans of the medical schools. In this controversy it had to be remembered that the London County Council was a political body and was larger than most of the parliaments of Europe. On the instructions of the council, a letter was sent to the chairman of the Central Public Health Committee of the London County Council expressing the hope that in spite of misunderstandings it would accept the offer of a friendly conference through suitably appointed representatives with a view to a solution that would insure the widest possible field of applicants to fill positions in the service, and the greatest efficiency of the service. There is really no reason why a satisfactory understanding should not be reached.

Deaths from Injection Treatment of Varicose Veins

In a previous letter (*THE JOURNAL*, May 14, 1932, p. 1754) it was pointed out that the injection treatment of varicose veins is not quite so safe as is generally supposed. Pulmonary embolism has generally been the fatal complication. In reviewing 120 cases in which he had performed necropsies, Sir Bernard Spilsbury found that the injection treatment of varicose veins was the cause of death in three cases in two of which sodium salicylate and in one of which sodium morrhuate had been injected. A little later another case was the subject of an inquest. A week after injection at the German Hospital, London a woman, aged 62 suddenly became faint while doing her housework and died before medical aid could be summoned. The necropsy showed that the cause of death was a tubular clot in the heart. Another fatal complication of the injection treatment has now come to light. An inquest was held on two patients who died of septicemia following the injection of sodium morrhuate for varicose veins, at a hospital. They were members of a group of twelve patients who were injected at the

same time. The majority did not suffer any ill effects, but in one case an abscess developed locally. In all three cases the causal organism was *Staphylococcus aureus*. The source of infection could not be determined. Infection from the needles was excluded. The 5 per cent sodium morrhuate solution was made up at the hospital according to a practice followed in a series of more than 10,000 injections without incident and involved sterilizing at a temperature just below boiling in the presence of 0.5 per cent phenol. But a specimen of the solid sodium morrhuate supplied to the hospital and sterilized there in bulk, gave a rich growth of a staphylococcus on blood agar after forty-eight hours' incubation. Possibly the sterilization in bulk presents greater difficulties than is supposed. It is stated that other cases of infection following injections of veins have occurred in other hospitals, but they have not had results to give rise to an inquiry.

Appeal to Diabetic Patients by H G Wells to Help Research

Asthma research in this country has been organized and financed by sufferers from the disease, which was a new departure in the promotion of research. In a letter to the *Times* Mr H G Wells the author, has invited his fellow sufferers from diabetes to follow this example. He points out that, thanks to a regulated diet and to insulin they are living active, happy lives, while a few years ago many would have been uncomfortable and dying slowly or already dead but for the work of a small group of experimenters and practitioners who have brought this particular maladjustment under control. He says that they can contribute to the research "that is still perfecting the very precise and beautiful treatment and help others not so well off. The diabetic department of King's College Hospital has been carried on for some time under increasingly cramped conditions and now has a special opportunity for expansion. In 1932 it dealt with 2,472 diabetic patients and the number still increases. Mr Wells suggests that the elect class of grateful diabetic patients should tax themselves for the benefit of the cult. He is rather surprised that they have not already formed an association to watch over and extend 'this most benign branch of medical science.'

The Key to the Leprosy Problem

Sir Leonard Rogers, the leading authority on leprosy speaking at a meeting of the British Empire Relief Association, said that, if infection of children could be prevented, leprosy would die out. The value, in not too advanced cases of injections of soluble forms of the active principle of chaulmoogra and hydrocarpus oils had now passed the realms of controversy. If the house contacts of all discovered cases were examined repeatedly for ten years to detect and clear up in the early stages—during which time the advanced cases would nearly all have become fatal—there would remain too few contagious cases to maintain the disease. The efficacy of this plan had been proved in Nauru Island in the Pacific and in the southern Sudan. In the Sudan, 6,500 cases were found in an infected area. The 4,800 infective patients were put into a colony and treated, and within the last year 2,230 had been discharged free from all signs of disease. Children were the key to the leprosy problem.

Tsetse Fly Control

The tsetse fly is still a great evil in many parts of Africa and prevents economic progress in large stretches of territory. Even in areas that are settled there is the danger that an advance of the fly may make a heavy toll of life. In extreme cases it may be necessary to evacuate the population and surrender the territory to the fly. The measures adopted for its destruction differ according to the kind of fly and even for the same fly in different districts, according to variations in the terrain and in the habits of the natives. They include destroy-

ing fly-infested bush by clearing or by fire erection of barriers to isolate the fly and infected game, and the wholesale catching of flies by hand or in specially made traps. By these methods, considerable areas of land have been made available for occupation. The Tsetse Fly Committee is confident that in suitable areas it will be possible to eradicate tsetse flies at relatively small cost. But for this special work technical knowledge will be necessary and, where wide areas are infested, a small organization of specially trained men must be maintained.

Outbreak of Typhoid

In the Malton urban district of Yorkshire, in six weeks 235 persons or 5 per cent of the population, contracted typhoid. The outbreak was due to pollution of the public water supply which is derived from a local well a source which the district council was urged forty years ago by the local government board to abandon by reason of its liability to pollution and the associated high incidence of diseases of the enteric group. On the present occasion the cause was access to the public water supply of the excreta of a typhoid patient who had been admitted to the public assistance institution and within two months 270 persons contracted the disease and 23 died. There were no cases of typhoid in the urban district until Sept. 23, 1932, when the patient mentioned was admitted to the institution. On September 26 he was found to be suffering from typhoid but he was not removed to an isolation hospital until October 26. His excreta were drained into the river Derwent—the common sewer of the town—by a broken drain, allowing soakage of part of its contents into the soil and polluting it with infection which gained access to the water supply. Malton had an exceptional incidence of typhoid during the seventies, eighties and nineties of the last century. It is noteworthy that this should have been repeated after such a long interval and have been due to the same vehicle. Improved sanitation is now being introduced.

Deceptive Methods in Medical Advertising

Competition between manufacturers of pharmaceutical products has led to the invention of shrewd or even deceptive, methods for attracting the attention of physicians to their special products. Series of lectures on cancer, held in the town-halls in the provinces, and having all the appearance of a scientific course for the promotion of health and having the endorsement of the minister of public health, have been found to be mere advertising schemes. The speaker, after a comprehensive discussion on cancer, which betrays no evidence of personal interest ends finally with an exposition of a mode of treatment and the recommendation of a pharmaceutical specialty as an infallible remedy, whereas an investigation often reveals that the lecturer is in the secret employ of the manufacturer of this remedy. Bombarded by complaints from physicians who had attended these lectures in the department of Charente-inférieure the prefect, on order of the minister, prohibited the continuance of the lectures. The mayors of rural communes have been instructed to refuse permission to hold lectures in municipal halls unless the lecturer agrees to abstain from all propaganda of a personal type. In another instance, the deception took a different form. A handsome young woman, tastefully attired, presented herself as a client at the consultation room of a number of dermatologists. She had come she stated, to inquire whether the physician would be able to remove certain tattoo marks that had become displeasing to her. The tattoo marks, as was revealed when she partially disrobed, spelled out the name of a pharmaceutical product. She explained then to the practitioner that, having been cured of a lingering disease by this marvelous product she had decided to have the name of

the product tattooed on her person as an enduring testimony of her gratitude. At the same time, she utilized her opportunity to laud the virtues of the product to the physicians. The physician smiled, told the young woman to dress, and usually sent her away without further discussion. Sometimes, however, a physician took the matter seriously and consented to remove the tattoo marks. In that case, a day was set for the operation but the young woman failed to appear. But the effect desired was produced and, in either event, the name of the product remained engraved on the mind of the physician.

Clinical Diphtheria in Some Vaccinated Persons

Cases of diphtheria arising in persons previously vaccinated against the disease are exceptional. They have been known to occur after even one year. It is assumed that the immunity conferred by the anatoxin was insufficient. The conclusion is that it is necessary to use an anatoxin with a high content of antitoxic units, and to administer rigorously, at intervals of fifteen days, the three injections required by Ramon. Mr Scapier has recently observed two peculiar and troublesome cases. Both children had been vaccinated in a perfectly proper manner, one three months and the other five months before being taken ill. Both patients were affected with pseudomembranous angina, the diphtherial character of which was clinically evident.

The false membranes when examined in the laboratory did not show the presence of Löffler's bacillus either by direct examination or on cultivation. Nevertheless, in view of the significant progressive development of the symptoms Scapier did not hesitate to administer copious injections of antitoxin, whereupon the symptoms promptly receded. In both cases the absence of Löffler's bacilli cast doubt on the diagnosis, but the success of the treatment was conclusive. Scapier raises the question: Did the Ramon anatoxin create an allergic state that prevented the development of Löffler's bacilli in their complete form but permitted nevertheless the development of the virus in a filtrable and invisible form, derived possibly from a vaccinated germ carrier, and against which the antidiphtheric serum was able to act from a clinical point of view (it being a recognized fact that the serum does not act directly against the bacilli but against the diphtheria toxin)?

Another Method for the Diagnosis of Pregnancy

The *Presse medicale* publishes an article by R. Masciottra and R. Martinez of Hoz which announces a simplification of the Aschheim-Zondek procedure for the early determination of pregnancy. It is based on a series of experiments all of which were concordant, which showed that the injection of the prehypophyseal hormone into the guinea-pig of either sex and irrespective of the dose, produces, within the first twenty-four hours, an increase of cholesterol in the blood amounting to from 30 to 50 per cent. The urine of pregnant women injected into the guinea-pig provokes exactly the same effects. The authors deduce from this fact that this reaction which is constant, will make it possible to simplify the application of the Aschheim-Zondek test. The guinea-pig is easy to handle and the determination of the cholesterol in its blood is easy with the Grigaut method of analysis, without its being necessary to kill the animal as is done when the rabbit, the rat or the mouse is employed.

Exchange of Children of Physicians During School Vacations

International exchanges of students between universities of different nationalities have become rather common in recent years. The Association professionnelle internationale des médecins, at its sixth annual session, in Budapest in 1931, was requested by one of its members, Dr Schaeftgen of Luxembourg, to assume the control of exchanges of children belonging

to the families of physicians. He emphasized the value of such an exchange of children of members of one of the thirty-one national groups of which the association is composed. A physician would need to pay only the traveling expenses of the child. Furthermore, the exchange being made between physicians' families, there is less hesitancy about sending a child into a foreign country, particularly if the exchange is preceded by a questionnaire giving full information. The idea was approved by the assembly on condition that the association would not be expected to assume the responsibility but would confine itself to establishing a connection between the various national groups, who would then perfect the details. It was decided that a report should be presented at the next session, by Dr Schaeftgen and Dr Drooglever Fortuyn (Netherlands), to determine the conditions to govern exchanges of children between families of physicians, also to draw up the questionnaire to be sent to each applicant, in order to determine the kind of life that would await the child at his destination. The report was presented at Budapest at the 1932 session, and was approved. The regional groups will make known their views at the London session next September.

BERLIN

April 24, 1933

Regulations Pertaining to Necropsies and Cremation

The federal minister of the interior, with a view to the enactment of a federal law governing necropsies, requested the federal bureau of health to secure from the governments of the various *länder* the regulations governing necropsies within their jurisdictions. In Prussia there are no uniform regulations. Necropsies are left to the discretion of the local authorities. It is planned to incorporate in the new federal law regulating necropsies uniform regulations governing cremation. Hitherto there have been no federal regulations governing cremation, and the laws of the *länder* are by no means uniform. A federal law pertaining to necropsies would provide that they may be performed only by licensed practitioners of medicine. The inquest or necropsy, must establish the fact and the cause of death. If the cause of death is not certain and if there is any suspicion that the deceased did not die a natural death, dissection of the body by the sanitary police must be ordered.

The Training of Neurologists

The Deutsche Gesellschaft für Innere Medizin requested its directorate, some time ago to inquire into the contention of psychiatrists that neurology at the universities be taught within the psychiatric-neurologic clinic and that furthermore general neuropsychiatric departments and department heads be created in the hospitals. The *gesellschaft* urged that for historical, practical, scientific and pedagogic reasons such a one-sided solution must never prevail. Neurology with respect to research, theory and practice should continue to be regarded as a legitimate branch of both internal medicine and psychiatry. Taking due account of local conditions and personal qualities both internists and psychiatrists should be allowed to practice in the field of neurology. In clinics of internal medicine and in hospital departments neurologic services should be carefully differentiated, as is already the case in psychiatric institutions. In any event, the specialist in internal medicine and nervous diseases must continue to be recognized.

Regulations Concerning Venereal Disease in Prisons

The Federal Council on Health proposed some time ago, regulations for combating venereal disease in prisons and they have been generally adopted by the *länder*. The provisions stipulate that a prisoner with a venereal disease, even though it may not at present show any clinical manifestations, must

accept the treatment that his condition requires. In case such treatment cannot be administered in that institution, the prisoner should be transferred to a suitable institution or hospital. Infective patients must be hospitalized under conditions that exclude transmission of the disease to others. Utensils used by the patient should be marked and restricted to the patient's use. Before the patient is released he should be reexamined, if possible, to determine whether he is still infective and, if so, his case should be reported to the health authorities.

Sex Instruction in the Schools

The Badische Gesellschaft für soziale Hygiene recently called a conference of teachers, pastors and physicians, who, after deliberation, set up the following criteria:

1 Sex instruction in the schools shall be extended to pupils 15 to 16 years of age and to corresponding age groups of the continuation industrial and trade schools.

2 The subjects covered by the instruction shall be (a) the relation between the sexual instinct and morality with especial emphasis on personal and social responsibilities, (b) the biologic aspects of propagation and (c) the connection between sexual instincts and health hazards.

3 Instruction in these subjects shall be delegated to the physician. If a suitable woman physician is available she should be given charge of sex instruction for girls.

4 Sex instruction should be given in connection with discussions on general hygienic problems in organized classes but not in too large groups. The instruction should cover a period of about two hours and should form a part of the regular curriculum.

Professor Wagenmann's Birthday

On April 5, Prof. August Wagenmann, occupant of the chair of ophthalmology at the University of Heidelberg, celebrated his seventieth birthday. In his native city Göttingen Wagenmann became an assistant under Theodor Leber. In 1892 he accepted a chair in the University of Jena, where he remained eighteen years, and in 1910 became Leber's successor in Heidelberg. Wagenmann's research has been chiefly in the field of pathologic anatomy. For his research on the results of division of the optic nerve, Wagenmann was awarded the Graefe prize. He published also a comprehensive work on injuries of the eye, with especial reference to injuries due to accidents. For many years, Wagenmann was secretary of the Deutsche ophthalmologische Gesellschaft, of which he is now president.

Personals

Prof. August Gärtner, the dean of German hygienists, celebrated in Jena his eighty-fifth birthday, April 18. Like so many German scientists, he received his first training at the military medical school. In 1884, he was summoned to the federal bureau of health as assistant to Robert Koch. Two years later, he obtained the chair of hygiene at the University of Jena, which he retained until 1914. He carried on scientific studies in many fields, a dysentery bacillus bears his name, but it was in the field of water hygiene that he became an eminent authority, his opinions being often sought by foreign countries.

Prof. Alfred Denker, an authority in laryngology, rhinology and otology and for many years ordinarius at the University of Halle, now residing in Munich, completed his seventieth year April 19. Professor Denker achieved fame through research on deafness, deafmutism and education of deafmutes. He introduced also new operative methods for chronic suppurations of the maxillary sinus, and for tumors of the nose and of the hypophysis.

Prof. Roderich Stintzing Is Dead

Geheimer Medizinalrat Roderich Stintzing, who from 1890 to 1924 was the director of the medical University Clinic in Jena, died April 6, aged 79. In collaboration with Pentzold he published the *Handbuch der gesamten Therapie*, which has passed through six editions and to which Stintzing contributed a number of important chapters. He prepared also a new edition of Roth's *Klinische Terminologie*.

March 29, 1933

Awards to Scientists

At the general meeting of the Imperial Academy of Japan, February 12, the special committee announced the awards of the imperial prizes and others for 1932. The imperial prizes were given to Dr. J. Tsuji of the Physical and Chemical Research Institute for his researches on the elasticity of light and to Prof. B. Suzuki, D.Sc., of the Kyoto Imperial University for his work on fatty acids. The academy prize was awarded to Prof. M. Ishimoto of the Tokyo Imperial University science department for his seismological observations. The emperor's wedding commemoration prize, contributed by the Osaka *Mainichi* (daily paper) was given to Prof. S. Kusano, D.Sc., of the Tokyo Imperial University for his work on fungi to Prof. C. Oguchi, D.M., of the Nagoya Medical College for his research on Oguchi's disease to Prof. Y. Furutake, D.M., of the Osaka Imperial University for his discovery of kynurenin, a crystal chemical compound, and to Prof. H. Nomura, D.Sc., of the Sendai University for his study on the pungency of ginger.

Studies of Menstruation in Working Girls

Dr. Y. Sato has been studying for a long time the physical and mental condition of young girls who work as conductors of motor busses. The municipal tramcar bureau of Tokyo in 1924, inaugurated the omnibus service in the capital and ever since has employed about 700 single girls as conductors. They work from 6 in the morning to eight in the evening, one drive covering 10 miles or so, which they do seven or eight times a day. Sato, a physician on the staff of the hospital attached to the municipal bureau, studied the duration of menstruation of 220 of these girls who came to his office to consult about diseases of women. They were from 17.3 to 32.2 years of age.

Menstruation in Working Girls

Duration of Menstruation	Number of Girls	Percentage
8-10 days	6	2.73
7 days	67	30.45
6 days	8	3.64
5 days	34	15.45
4 days	47	21.36
3 days	40	18.18
2-1 days	5	2.27
0 days	13	5.91

Since they began this bus work among 140 girls examined, 24 girls had an increased flow while 12 had a decreased flow, 15 menstruated a longer time and 22 for a shorter time, 59 had more pain, while 3 stopped having pain. These changes occurred mostly from four to six months after they were employed, but gradually these changes disappeared and they menstruated as formerly.

Decrease in Medical Students

The entrance examinations for medical and pharmaceutical colleges were held as usual, this month throughout the country. The number of candidates was considerably smaller, to the astonishment of the authorities. Last year some private colleges were charged with accepting bribes from candidates for entrance. At that time the education office said it would supervise the examinations more closely. The decrease in the number of candidates is attributed partly to this and partly to the business depression. One pharmaceutical college that was censured last year had only 660 candidates this year as compared to more than 1,200 in the previous year. Of the eight private medical colleges and two pharmaceutical colleges in Tokyo, the Keio Medical College had an increase of only ninety this year, but the rest had a decrease.

March 31, 1933

Draft of the New Law on Social Insurance

In the new Rumania there are three systems of social insurance—one in Transylvania, by which system all districts comprising two or three counties have autonomous organizations, another system in the old kingdom, and the third one in Bessarabia. The government has not as yet interfered with the administration of the three organizations. Now a new law has been drafted to unify the three systems. The principal paragraphs of the proposed law are as follows:

Compulsory insurance is ordained for all classes of employees for sickness, invalidity and accidents, without regard to their age, sex or nationality, if their wages do not exceed the fixed maximum. Also independent craftsmen may become insured under special conditions enumerated in the law. The restrictions are as follows: The employees of state enterprises who were insured by their own special benefit societies before this law is enacted may continue this insurance with their societies, provided the benefits supplied by them are at least as much as is required by the new law. For this reason these special societies are obliged to have their regulations approved by the central board of social insurance. Apprentices and unpaid probationers, also members of the families of employers, must be insured. The pay office in Transylvania and the Banat will merge and their members continue to avail themselves of the insurance corresponding to the requirements of the law. The employees of the state, counties, municipalities or other public institution to whom the general pension law does not refer, are obliged to take out insurance against sickness and invalidity. Employees of the foregoing public institutions who have no pension are not obliged to be insured for old age and invalidity. The latter categories of employees may apply to the central board of social insurance for permission to be insured against sickness, but only under special contracts made with their organizations.

The insured are entitled to medical attendance, drugs and dressing materials, a monetary subsidy in case of sickness, accidents, maternity and death and a whole or partial invalidity pension. Medical treatment is extended also to a wife living with her husband, to children under 16 years of age, and to disabled parents. If hospital treatment is needed, the insurance office pays for attendance up to twenty-six weeks but the insurance council may lengthen this period to one year at most.

If financial conditions permit the office may pay the cost to members of sojourns at climatic resorts and mineral springs, and of dental prostheses. Relatives get drugs only. A monetary subsidy is paid for twenty-six weeks only.

Maternity help is given to an insured person for twelve weeks, the sum of the subsidy is equal to that allowed in case of sickness. After this, the mother is entitled to a six weeks nursing subsidy. The wife of an insured person is entitled, in case of childbirth, only to free medical attendance and drugs, but if the financial condition of the insurance office allows she may get 50 per cent of the subsidy, due to her husband, for six weeks.

An invalidity pension is granted to members who owing to old age, accident or sickness, are not able to earn one third of what they earned when in full health. The pension consists of a fixed sum. Pensioners get free medical attendance and drugs, in case of death, the relatives get a burial subsidy. The wife of a deceased pensioner, if disabled and poor gets 50 per cent of the pension of her late husband, children under 16 get one third of the pension of their late parents. The sum total of the pension of the widowed mother and orphan children cannot exceed the sum of the pension which the father received.

Half of the charges for insurance have to be paid by the employer and half by the employee. The weekly charges are

fixed by the general meeting of the central office and has to be sanctioned also by the council of ministers. The state contributes to the invalidity burden 15 000 000 lei yearly and later will add some state obligations and treasury notes, the amount to be fixed at a later date.

SICK BENEFIT CLUBS

Not less than 10 000 members may form a sick benefit club in any one district. The sick benefit clubs are administered as follows: A council, consisting of from twelve to twenty-four members with an equal number of employers and employees, is appointed on the recommendation of the chamber of commerce and trade and the chamber of work, by the minister of public works. The minister appoints three members, consisting of one physician, one engineer and one lawyer. The council prepares the budget, settles affairs pertaining to its sphere of action and appoints clerks and an auxiliary medical staff. The control committee manages the agenda of the general meeting and the finances. The medical committee, of from three to seven members, has as its president the physician-in-chief, who gives advice in medical affairs.

The central sick benefit club controls the other clubs and handles the funds. Its personnel is made up of the general assembly, the administrative council and the general management. The general assembly is made up as follows: The administrative council of every club delegates two employers and two employees, if a club has more than 25 000 members, it delegates four members. All the late ministers of public work are members. The manufacturers, craftsmen, employees, physicians, pharmacists, engineers and so on in all eleven such groups, contribute nineteen members. The national medical association is represented by two members. The professor of social politics at Bucharest University is a member. The ministries supply ten members. Two senators are delegated by the senate, to hold office for four years. The general assembly expresses its opinion on drafts of bills, determines the maximal wages for those intending to be insured, determines the categories of subsidies, and elects the administrative council and the executive committee.

THE MEDICAL ORGANIZATION

The Medical organization of the social insurance scheme comprises the following medical categories: (a) Physicians of the central institutions, the physicians-in-chief and medical inspectors of the sick benefit clubs, who are in the same category as the physicians of the public health directorate. The chief physicians of the social insurance in regard to salary are on a par with the medical chiefs of the county. Hospital physicians, radiologists, bacteriologists and pharmacists get the same salaries as those appointed by the public health directorate. (b) Hospital and sanatorium physicians, likewise the chief physicians of the outdoor departments, radiologists, bacteriologists and specialists, who attain their position by competitive examinations. (c) Assistant physicians, who get their appointments by entrance examinations. In case of epidemics contract physicians may be employed. In larger centers on the request of the directorate of the respective sick benefit clubs, 'free choice' medical service can be had. The minister has the right to suspend the execution of any resolution.

PUNISHMENT

Fines ranging from 2 000 to 10 000 lei and imprisonment from fifteen days to two months may be imposed on employers, clerks or physicians who issue false documents and certificates. In the case of physicians, a decision can be made only by the medical councils.

The Association of Balkan Physicians

The physicians of Yugoslavia, Bulgaria, Greece and Rumania have found an association to further medical science. The

Rumanian section held its constitutional meeting last week, under the presidency of professor Marinescu of the Bucharest university. The main point for discussion was the request of the association for cooperation in regard to the prophylaxis of tuberculosis and malaria. The Rumanian section accepted the principles of the union. The secretary of the Rumanian section occupies the house of the Rumanian Medical Association, Bucharest, Strada Isvor No 16.

Public Health in Rumania

According to statistics published by the ministry of health in 1932, 80,000 persons with open tuberculosis are on the register, the majority of whom are in special hospitals. Those in their homes are periodically supervised by the nearest dispensary medical officer. Of 20,000 trachoma patients registered, 10,000 are in Bessarabia. The number of registered pellagra patients in the past year was 47,872. The fight against these diseases cost 20 million lei last year.

Can Rats Survive After Suprarenalectomy?

Ever since Lewis demonstrated in 1921 that the majority of white rats survive the complete removal of the suprarenals, the fact has been confirmed in hundreds of rats at Buenos Aires and in Rosario. Nevertheless experiments recently performed by some American workers led to different results. The survival or death of the rats depends on the nutritional condition of the animals when the experiment is done. Rats bred at the Instituto de Fisiologia of Buenos Aires and Rosario and fed on bread and milk survive at a rate of from 50 to 100 per cent at the end of the first month after suprarenalectomy, while rats recently brought from some other breeding places and deprived of their suprarenals at the same time die at a rate of from 70 to 100 per cent in the first month following the operation. However, if the rats brought from some other breeding places are kept and fed at the Instituto de Fisiologia for a month or so before the operation and if the animals have not infected lungs, they survive the operation in a rate of from 50 to 100 per cent. The symptoms of suprarenal insufficiency of the surviving animals last about three weeks. Then the animals slowly and gradually compensate. The grave symptoms following suprarenalectomy disappear on the administration of extract of the suprarenal cortex. In the entire group of surviving animals, accessory suprarenals appear at the end of the first month or a month and a half after suprarenalectomy has been performed. During the first fifteen days following the operation the accessory suprarenals are not discoverable, but later on they appear, a fact that was pointed out last year by Lascano Gonzalez.

Scholarships for Graduate Studies

Dr Rodolfo Lobo was awarded the scholarship given by the Devoto Foundation, for 1932, to study toxicology in Europe. Drs Odoriz and Castro O Connor were awarded the scholarships recently created by the Prince of Wales at the Oxford University to study physiology of the nervous system and endocrinology, respectively. Dr J Cid of Rosario was awarded one of the Guggenheim scholarships for 1932 in the United States, to study histopathology of tumors of the nervous system. Dr Orias returned from the United States after a stay of two years at Western Reserve, Harvard and Woods Hole and other research centers in the United States. Dr J M Lascano Gonzalez will soon return from Freiburg after working two years and a half with Professor Aschoff. Dr Orias was awarded a scholarship of the University of Buenos Aires and another scholarship of the Rockefeller Foundation.

Treatment of Hydrocyanic Acid Poisoning

Dr Hug, professor of pharmacology of the Faculty of Medicine of Rosario, has reported the results of experiments which tend to elucidate the mechanism of the treatment of hydrocyanic acid poisoning. Reports of his experiments performed during the last three years have been published in the *Revista de la Sociedad argentina de biologia* and other medical journals. According to Professor Hug, the substances capable of action on hydrocyanic acid may be classified into three groups: substances that contain sulphur, sugars and their derivatives, and methemoglobin-producing substances. In the first group are sodium thiosulphate, glutathione, cystine and some other substances, the most active substance seems to be sodium tetrathiocyanate, which, according to work performed by Chistoni and Foresti, is capable of transforming in vitro cyanides into sulphocyanides. While the second group has not been as yet studied by the author, according to experiments by Forst and Rentz it seems that preference should be given to dioxyacetone. In the third group the best results were obtained with sodium nitrite. To prove the therapeutic value of these substances, dogs were injected subcutaneously with progressive doses of hydrocyanic acid. As soon as the first grave symptoms of hydrocyanic intoxication appeared, the animals were given an injection of a solution of the antidote intravenously. Four antidotes were tested and the results obtained were as follows:

Dogs given an intravenous injection of sodium thiosulphate, sodium tetrathiocyanate, methylene blue or sodium nitrite in doses of 1 or 1.5 Gm, 0.2 Gm, 18 mg and 40 mg, respectively, per kilogram of body weight, at the appearance of toxic symptoms caused by the subcutaneous injection of 1, 2, 3, 2 or 4 fatal doses of hydrocyanic acid, respectively, did not die in the experiment. Larger doses than 0.2 Gm per kilogram of body weight of sodium tetrathiocyanate are toxic. Pyrogallol, pyrocatechin, phenylhydrazine and potassium ferrocyanide are also methemoglobin producing substances. Potassium ferrocyanide, however, has an antidotal action only when in presence of laked corpuscles, since it does not permeate the erythrocytes. Professor Hug at present gives his greatest attention to methemoglobin-producing substances. He has been able to note that the hemoglobin derivatives that are formed with various substances do not fix hydrocyanic acid in the same manner in which methemoglobin forming substances do. Methemoglobin formed by sodium nitrite fixes hydrocyanic acid in an equimolecular proportion (taking 16,700 as the molecular weight of hemoglobin). According to the author, the fundamental reason for the neutralization of the poison by these substances is the fixation of the hydrocyanic acid by the methemoglobin in the blood. The limitation of the antidotal activity of sodium nitrite depends on the maximal quantity of hemoglobin changeable to methemoglobin, without killing the animal by anoxemia. In the dog a dose of 40 mg of sodium nitrite per kilogram of body weight is the maximal dose and this may kill the animal in some cases. This dose changes more than 50 per cent of the hemoglobin into methemoglobin. These studies indicate that the almost simultaneous administration of antidotes of the different groups may result in a summation of effects. Hug notes the excellent results reported by Geiger and by Hanzlik in THE JOURNAL (Dec 3 1932, p 1944, Feb 4, 1933, p 357) from the use of methylene blue as an antidote. He believes that his experiments indicate that the results obtained with sodium nitrite ought to be even better. Since the tolerance of man to sodium nitrite is not yet known, the author advises the slow injection of a 20 per cent solution not to exceed the total dose of 1 Gm (50 cc of this solution) for an adult. The author advises the alternate use of injection of sodium nitrite with intravenous injections of 10 cc of a 3 per cent solution of sodium thiosulphate.

Marriages

CHARLES HOWARD KINGSBURY Gillett, Wis, to Miss Grace Campbell of Milwaukee in Chicago, April 13

HERBERT RICHARDSON DOVE, Colonial Heights, S C, to Miss Helen Turner of Spartanburg, April 8.

BEN W BIRD, JR., Princeton, W Va, to Miss Lucile Dunlap of Cairo, Ill, April 9

WILLIAM HOBSON WOODY to Miss Sarah Anne Melher, both of Baltimore, April 24

ROBERT LOUIS LEE, Kansas City, Kan, to Miss Robbie Archer at Turner, March 4

Deaths

Henry Andrews Cotton ♂ Lawrenceville, N J, University of Maryland School of Medicine, Baltimore, 1899, member of the House of Delegates of the American Medical Association 1921-1922, member of the American Neurological Association, American Psychiatric Association, New England Society of Psychiatry, Association for Research in Nervous and Mental Diseases, American Psychopathological Association and the Society of American Bacteriologists, veteran of the Spanish-American and World wars, corresponding member of the British Medico-Psychological Society, for many years medical director of the New Jersey State Hospital Trenton, author of "Defective, Delinquent and Insane", aged 56, died May 8, in Trenton, of angina pectoris and coronary embolism

Byron Bennett Davis ♂ Omaha, Minnesota Hospital College, Minneapolis, 1884 member of the House of Delegates of the American Medical Association in 1902, professor of principles of surgery and clinical surgery and chairman of the department, University of Nebraska College of Medicine, past president of the Nebraska State Medical Association, member and past president of the Western Surgical Association on the staffs of the Immanuel Deaconess Institute, Bishop Clarkson Memorial and the Nebraska Methodist Episcopal hospitals, aged 73, died, April 20, of carcinoma of the colon

Cyrenus G Darling, Ann Arbor, Mich University of Michigan Medical School, Ann Arbor 1881 member and past president of the Michigan State Medical Society fellow of the American College of Surgeons formerly professor of surgery at his alma mater for four years acting dean of the dental college of the University of Michigan at one time mayor of Ann Arbor, for many years chief of staff at St. Joseph's Mercy Hospital, aged 77, died, April 21, of pernicious anemia

Henry Joseph Scherck ♂ St Louis Tulane University of Louisiana Medical Department, New Orleans, 1889, member of the American Urological Association, fellow of the American College of Surgeons, assistant professor of urology, St. Louis University School of Medicine aged 65, on the staffs of the Missouri Pacific Hospital St Louis City Hospital, Jewish Home for Chronic Invalids and the Jewish Hospital, where he died March 29 of heart disease.

Philip Webb Davis ♂ Portland Maine, Medical School of Maine, Portland, 1900, secretary of the Maine Medical Association, fellow of the American College of Surgeons served during the World War, for twenty-seven years member of the staff of the Maine General Hospital editor of the *Maine Medical Journal* aged 57 was drowned April 26 when the automobile which he was driving crashed through the wooden railing of a narrow bridge.

Alphonso David Rockwell, Flushing, N Y Bellevue Hospital Medical College New York, 1864, professor of electrotherapeutics, New York Post-Graduate School of Medicine, 1888-1892, past president of the American Electro-Therapeutic Association, Civil War veteran, neurologist and electrotherapist to the Flushing Hospital, 1904-1912, author of *Relation of Electricity to Medicine and Surgery*, and other works, aged 92, died, April 12

Nathan Sturges Jarvis, Major, U S Army retired, New York, Bellevue Hospital Medical College 1884 entered the army as an assistant surgeon in 1887 veteran of the Spanish-American War, was retired in 1901 for disability in pursuance of a special act of Congress returned to active duty in 1901 served during the World War retired as a major in 1930, aged 72, died, April 20, of angina pectoris

Winthrop Essex McGinley, New London, Conn, College of Physicians and Surgeons, Baltimore, 1914 member of the Connecticut State Medical Society, past president and secretary of the New London County Medical Society, served during the World War, on the staff of the Lawrence and Memorial Associated Hospitals, aged 47, died suddenly, April 27, in Waterford, of heart disease.

William Wertenbaker ♂ Wilmington, Del University of Virginia Department of Medicine, Charlottesville 1901, fellow of the American College of Surgeons, gynecologist and obstetrician to St. Francis and Wilmington General hospitals, gynecologist to the Delaware State Hospital, Farnhurst, consultant on the surgical staff of the Kent General Hospital, Dover, aged 57, died, March 24

Jere Williams Lord ♂ Baltimore, University of Pennsylvania School of Medicine, Philadelphia, 1887 for many years clinical professor of dermatology, Johns Hopkins University School of Medicine aged 69 on the staffs of the Johns Hopkins Hospital and the Union Memorial Hospital where he died, April 23, of diverticulitis, fecal fistula and abdominal abscess

Lon West Haynes, Detroit, University of Michigan Medical School, Ann Arbor, 1908, member of the Michigan State Medical Society, fellow of the American College of Surgeons, aged 49 on the staffs of the Receiving Hospital Herman Kiefer Hospital and the Harper Hospital, where he died, April 19, of coronary thrombosis

John J Rooks, Grand Rapids, Mich, Grand Rapids Medical College 1901, College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1902 member of the Michigan State Medical Society, on the staff of St. Mary's Hospital, aged 55, died suddenly, April 17, of coronary thrombosis

George W McAllister ♂ Hampton Va University College of Medicine, Richmond, 1899, fellow of the American College of Surgeons on the staff of the Hampton Training School for Nurses and Dixie Hospital, aged 56, died, March 30, of acute nephritis, paresis and therapeutic quartan malaria.

Edwin H Underwood ♂ Fort Wayne Ind, Hahnemann Medical College and Hospital, Chicago, 1905 served during the World War aged 61, on the staff of the Lutheran Hospital, where he died, April 3 of septicemia, following a slight wound from an instrument, incurred while treating a patient

James Fleming Musser, Calvin, Okla., Chicago College of Medicine and Surgery, 1912 member of the Oklahoma State Medical Association served during the World War aged 48, died, April 17, in a hospital at Holdenville, of injuries received when his automobile overturned.

Mae Lichtenwalner-Myers ♂ Philadelphia Woman's Medical College of Pennsylvania, Philadelphia, 1905 professor of histology and embryology at her alma mater, member of the American Association of Anatomists aged 50, died, April 28, in the Woman's Hospital of heart disease

Alexander H Stewart ♂ Lawton Okla, Medical College of Ohio, Cincinnati, 1882 president of the Comanche County Medical Society, veteran of the Spanish-American War, for merly member of the state legislature of Kentucky, aged 80, died, April 10 of cerebral hemorrhage.

William James Wolfe, Chatham N J, University of the City of New York Medical Department, 1884, member of the Medical Society of New Jersey, past president of the Morris County Medical Society formerly postmaster, aged 73, died, March 31, of pulmonary edema.

William Archibald Young, Toronto Ont, Canada Victoria University Medical Department, Coburg 1886 L.R.C.P. London 1887 for thirty-five years coroner for the city of Toronto editor of the *Canadian Journal of Medicine and Surgery* aged 66, died, April 1

William Bulger Johnson, Birmingham Ala, University of the South Medical Department, Sewanee, Tenn 1905, member of the Medical Association of the State of Alabama, aged 53 died suddenly, March 26, at Blount Springs, of chronic endocarditis and myocarditis

Harrison Murray Crittenden, Haverhill Mass, Tufts College Medical School, Boston, 1898, member of the Massachusetts Medical Society aged 58 on the staff of the General Stephen Henry Gale Hospital, where he died, April 5, of pulmonary embolism.

Benjamin Franklin Roller, Chicago, University of Pennsylvania School of Medicine, Philadelphia, 1902 member of the Medical Society of the State of New York, and the Illinois State Medical Society aged 56, died, April 20, in the Doctor's Hospital, of pneumonia

Rayburn B Smith ♂ Alma, Mich., Saginaw (Mich.) Valley Medical College, 1903, formerly bank president and mayor of Alma for eight years president of the school board, aged 51, died, April 21, in the Saginaw General Hospital, of typhoid

Valerian Albert Miller ♂ Lake Arthur, La., Vanderbilt University School of Medicine Nashville, Tenn., 1895 past president of the Jeff-Davis Parish Medical Society for twelve years coroner of Davis Parish, aged 60, died, April 18, of heart disease.

Eugene McDowell Trabue, Louisville, Ky., University of Louisville School of Medicine, 1915, served during the World War, chief of the tuberculosis unit of the medical staff of the Veterans' Administration, aged 43, died, April 8, of heart disease

Mendel Emmanuel Jonesoff, New York, University of Paris Faculty of Medicine, Paris France, 1900, member of the Medical Society of the State of New York, aged 64, died, April 4 in the French Hospital of angina pectoris and arthritis

James Philip Hatfield, Wheat, Tenn. Lincoln Memorial University Medical Department, Knoxville, 1912, member of the Tennessee State Medical Association, aged 50, died April 7, in Knoxville (Tenn.) General Hospital, of cerebral hemorrhage

Charles Hawkins Gilmour, Toronto, Ont., Canada, University of Toronto Faculty of Medicine, 1903 fellow of the American College of Surgeons, served during the World War, on the staff of the Grace Hospital, aged 53, died, April 20

Leverette Herbert Price, Moncton, N B, Canada, Bellevue Hospital Medical College, 1892 member and past president of the Council of Physicians and Surgeons of New Brunswick, aged 65, died, March 1, in the City Hospital

Arthur P Ginn, Nebraska City Neb., University of Vermont College of Medicine, Burlington 1883, past president and secretary of the Otoe County Medical Society, aged 71, died, April 4, in Los Angeles, of cerebral hemorrhage.

Frank Peter Stedem, Champaign, Ill., Eclectic Medical Institute, Cincinnati 1899 served during the World War, formerly mayor and member of the board of health of Saybrook, aged 68, died, April 14, of cerebral hemorrhage

Emmett L Robinson, Lincoln, Neb., College of Physicians and Surgeons, Keokuk, Iowa, 1878, also a pharmacist, formerly member and secretary of the school board of Central City, aged 82, died, April 9, of perforated gastric ulcer

Wyman Smith, Minneapolis Northwestern University Medical School Chicago, 1931, member of the Minnesota State Medical Association, aged 29 on the staff of St Barnabas Hospital, where he died, April 20, of septicemia

Henry House Beers, New York University of Vermont College of Medicine, Burlington, 1901 consulting ophthalmologist to the Rockaway Beach (N Y) Hospital, aged 57, died, April 23, of carcinoma of the left lung and liver

Clyde F Johnson, Seymour, Texas, Hospital College of Medicine Louisville, Ky., 1901 member of the State Medical Association of Texas, aged 63, on the staff of the Baylor County Hospital, where he died April 6, of peritonitis

George M Waterhouse, Weiser Idaho, Eclectic Medical Institute, Cincinnati, 1885, Barnes Medical College, St Louis, 1899, member of the Idaho State Medical Association, aged 72, died March 6, in St. Luke's Hospital, Boise.

Frederick Church Jacobson, Newark N J Medical Department of the University of the City of New York, 1894, member of the Medical Society of New Jersey aged 64 died, April 11, of carcinoma of the bladder and prostate

Solomon Nathan Rosenbaum, New York Medical Department of the University of the City of New York, 1895 member of the Medical Society of the State of New York, aged 73, died April 2, of cerebral thrombosis

Joseph G Russell, Salem N Y Hahnemann Medical College and Hospital Chicago 1879, aged 74 died April 10, in the Dover (N J) General Hospital of a skull fracture received when he was struck by an automobile.

Charles B Dreher, Tamaqua, Pa., Homeopathic Medical College of Pennsylvania, Philadelphia, 1867, for many years bank president and formerly secretary of the school board, aged 87 died April 7, of cerebral thrombosis

Ignatz David Loewy, Whipple, Ariz. Jefferson Medical College of Philadelphia 1903 on the staff of the Veterans Administration Hospital aged 52 died April 10, of tuberculosis of the lungs and tumor of the brain

Nathaniel Albert Nicholson, Back Bay, Va., University College of Medicine, Richmond, 1901, member of the Medical

Society of Virginia, aged 52, died, April 3, in St Vincent's Hospital, Norfolk, of tumor of the brain

Thomas Leiper Kane, Chicago, School of Medicine of the Division of the Biological Sciences of the University of Chicago 1932, aged 29, died, April 13, in the Billings Memorial Hospital, of streptococcal meningitis

John Joseph Smith, Dallas, Texas Baylor University College of Medicine, Dallas 1916, member of the State Medical Association of Texas aged 56 died March 21, in a local hospital, of carcinoma of the thyroid.

George Crofton Enright, Yonkers, N Y University of Vermont College of Medicine, Burlington 1903 member of the Medical Society of the State of New York, aged 57, died, April 12, of cerebral hemorrhage.

Samuel W Gadd, Philadelphia University of Pennsylvania School of Medicine, Philadelphia 1885, member of the Medical Society of the State of Pennsylvania aged 74, died, April 10, of coronary thrombosis

Charles Menzies Briggs, Fairport N Y, University of Buffalo School of Medicine, 1880 member of the Medical Society of the State of New York, aged 77, died, April 3, in the Rochester General Hospital

Milton Walton ♂ Hastings Fla Memphis (Tenn.) Hospital Medical College 1904, president of St Johns County Medical Society served during the World War aged 51, died, April 23, of heart disease

John E Minney, Altadena, Calif., Kansas City (Mo) Medical College, 1880 formerly dean and professor of ophthalmology and otology, Kansas Medical College, Topeka, aged 87, died, April 7, of pyonephrosis

John Chisholm Breedlove, Muldrow, Okla. Washington University School of Medicine, St. Louis 1908 member of the Arkansas Medical Society, aged 49, died suddenly April 14, of heart disease

George C Traugh ♂ Donora, Pa., National Normal University College of Medicine Lebanon Ohio 1896 also a preacher and lawyer, aged 69, died suddenly, March 30, of acute myocarditis

Nellie Florence Moore Hegardt, Los Angeles College of Physicians and Surgeons, Los Angeles 1914 aged 63 died March 9, of sarcoma of the orbit, sternum and ribs and intestinal obstruction

Percy F Houghton, Brooklyn Georgetown University School of Medicine, Washington, D C, 1901 served during the World War aged 57, died, April 14, in St Catherine's Hospital, of goiter

Charles John Loizeaux, Des Moines, Iowa State University of Iowa College of Homeopathic Medicine, Iowa City, 1889, aged 84, died, April 1, of cerebral hemorrhage and arteriosclerosis

George William Fegers, Nebraska City, Neb. Keokuk (Iowa) Medical College, 1896 member of the Nebraska State Medical Association, aged 59, died suddenly March 31, of angina pectoris

James Madison Wellborn, Rock Springs, Ga. Chattanooga (Tenn.) Medical College, 1893 served during the World War, aged 64, died, April 6, in the Erlanger Hospital Chattanooga

Chauncey Centus Way, Muskogee, Okla. Chicago Homeopathic Medical College 1904, Hahnemann Medical College and Hospital, Chicago, 1905 aged 56, died February 6 of lobar pneumonia

Robert Pearl Woods ♂ Oak Hill W Va College of Physicians and Surgeons, Baltimore, 1913 medical superintendent of the Oak Hill Hospital, aged 47, died, April 16, of pneumonia

Wilbur Mason Warner, Middletown, Ohio Pulte Medical College, Cincinnati, 1897, member of the Ohio State Medical Association, aged 64, died, April 11 of carcinoma of the bladder

Edward Grant May, Toledo, Ohio, Northwestern Ohio Medical College Toledo, 1887 served during the World War aged 68 died April 8 in St. Vincent's Hospital of pneumonia

Frederick Fobes Doggett, Boston, Harvard University Medical School Boston 1880 member of the Massachusetts Medical Society, aged 78 died, April 13, of chronic nephritis

John Copps Bowker, Lawrence, Mass., Medical School of Maine Portland 1884, aged 71 died, April 20, at St Petersburg, Fla., of injuries received when he fell in a bath tub

Emil Besser, Remington, Ind., Chicago Homeopathic Medical College 1899, member of the Indiana State Medical Association, aged 65, died, April 14, of pneumonia

Hugh Lownds Appleton, Gadsden Ala., Vanderbilt University School of Medicine, Nashville, Tenn., 1892, aged 67, died, April 16, of pyemia and abscess of the lung

John A. White ⊕ Indianapolis, University of Georgia Medical Department Augusta, 1915 served during the World War, aged 44, died, April 9, of heart disease.

Harvey J. Churchill, Pekin Ill. National Homeopathic Medical College, Chicago 1893 aged 85, died, April 14 in Los Angeles, of complications resulting from a fall

Walter C. Skiff ⊕ New Haven, Conn. New York Homeopathic Medical College 1883 aged 75 died, April 23, of coronary thrombosis, edema and myocarditis

Charles A. Reed, New Castle, Pa. Miami Medical College Cincinnati, 1885 member of the Medical Society of the State of Pennsylvania, aged 75, died, February 23

Robert Allen Gamble, Petersburg Va., St. Louis College of Physicians and Surgeons 1896 aged 59, was instantly killed, April 14, in an automobile accident.

George Winters Herbern, San Francisco, Jefferson Medical College of Philadelphia, 1902, aged 62 died, March 9, in St. John's Hospital, of pernicious anemia

Horace Leon Cunningham ⊕ Amar, Ala., Vanderbilt University School of Medicine, Nashville, Tenn., 1910, aged 49 died, in April of coronary occlusion

John Christian Martin, Kansas City Mo., University of Louisville (Ky.) School of Medicine, 1897, aged 59 died April 11, of a self inflicted bullet wound

Frank D. Bishop, Monrovia, Calif. Cleveland University of Medicine and Surgery, 1894 aged 76, died, March 9, of carcinoma of the prostate and bladder

Allan Holford Walker, Toronto Ont. Canada Royal College of Physicians and Surgeons Kingston 1867, aged 87, died, February 23, of angina pectoris

Aurelius L. Petree, Greensboro N. C. College of Physicians and Surgeons, Baltimore 1886 aged 74, died April 16, of angina pectoris and myocarditis

Wiley L. Whitehead, Lake City S. C. Maryland Medical College Baltimore 1904, aged 59 died, March 31 of injuries received in an automobile accident.

Joseph H. Close, Topeka Kan. Rush Medical College Chicago 1894 aged 68 died, April 7, of carcinoma of the left kidney with metastasis

Samuel King Carson, Palo Alto Calif. Ohio Medical University, Columbus 1898, aged 68, died, March 17 of carcinoma of the bladder

Frederick L. Tupper ⊕ Flint, Mich. Michigan College of Medicine and Surgery, Detroit, 1894, aged 74, died April 21 of heart disease.

Helen B. Bodelson, Rock Island Ill. Woman's Hospital Medical College Chicago 1878 aged 91, died, April 13, of bronchopneumonia

Charles Foley, Dearborn Mich. Detroit College of Medicine, 1891, aged 85, died, April 10, of coronary thrombosis and myocarditis

William Ledmon Allen, Oakland Calif. University of Buffalo School of Medicine, 1878, aged 86, died, March 28 of heart disease.

George W. Weyl, Pasadena Calif., Eclectic Medical Institute Cincinnati, 1889, aged 66, died suddenly April 15, of heart disease.

Mary Parks Putnam, Los Angeles College of Physicians and Surgeons, Boston, 1894 aged 91 died March 7, of chronic myocarditis

George Edens, Danville Ill. Hahnemann Medical College and Hospital, Chicago, 1879, aged 81, died, April 17, of cerebral softening

David G. Stewart, Ironton Ohio, Columbus Medical College 1891, aged 76 died, March 9, of diabetes mellitus

Charles P. Felshaw, Holly Mich., Detroit Medical College, 1877, aged 92, died April 8, of bronchitis

Irene Salgo, New York, University of Szeged, Hungary, 1923 aged 35 died, April 8 of epilepsy

Goodson Cox, Mount Ida Ark. (licensed Arkansas, 1903), aged 87, died, February 23, of senility

Bureau of Investigation

MISBRANDED "PATENT MEDICINES"

Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the United States Department of Agriculture

[Editorial Note The abstracts that follow are given in the briefest possible form (1) the name of the product (2) the name of the manufacturer, shipper or consigner, (3) the composition, (4) the type of nostrum, (5) the reason for the charge of misbranding and (6) the date of issuance of the Notice of Judgment—which may be considerably later than the date of the seizure of the product]

Teaoo Ointment.—White & Kleppinger Inc. Chicago Composition Ointment with petroleum base containing methyl salicylate camphor menthol and a trace of boric acid Cure all Fraudulent therapeutic claims.—[N J 17832 June 1931]

Pastillas de Compuesta Mitohella.—Dr. J. H. Dye Buffalo N. Y. Composition Extracts of plant drugs including resins and volatile oils coated with starch sugar and calcium carbonate For female disorders. Fraudulent therapeutic claims.—[N J 17834 June 1931]

Welch's Sweet Lilly.—A. J. Welch New Orleans Composition An ointment with a petrolatum and paraffin base containing camphor and peppermint oil For croup lagrippe pneumonia coughs asthma piles and toothache. Fraudulent therapeutic claims.—[N J 17837 June 1931]

Callente Oil.—International Drug Sales Co. Denver Composition Methyl salicylate camphor extracts of plant drugs including capsicum chloroform alcohol (47 per cent) and water Cure oil Fraudulent therapeutic claims.—[N J 17838 June 1931]

Cerolactol Aniliseptic Ointment.—Hibbs Worth Laboratories Inc. Chicago Composition An ointment essentially of petrolatum and paraffin, with tar zinc oxide sulphur and traces of cerium and phosphorus compounds. For eczema etc. Fraudulent therapeutic claims.—[N J 17840 June 1931]

Cerolactol Internal Aniliseptic Tablets.—Hibbs Worth Laboratories, Inc. Chicago Composition Charcoal phenolphthalein with a small amount of a cerium compound starch and peppermint oil coated with sugar and starch For stomach disorders etc. Fraudulent therapeutic claims.—[N J 17840 June 1931]

Cerolactol Germicide and Prophylactol.—Hibbs Worth Laboratories Inc. Chicago Composition Boric acid menthol thymol phenol salicylic acid a trace of a cerium compound glycerin alcohol and water For mouth and throat affections Fraudulent therapeutic claims.—[N J 17840 June 1931]

Taylor's Bromo Aspirin.—Taylor Medicine Co. Tampa Fla. Composition Acetylsalicylic acid (aspirin) and caffeine but no bromine nor bromide. For fevers lagrippe rheumatism etc. Fraudulent therapeutic claims.—[N J 17844 June 1931]

Sniff.—M. R. Cady & Co. Grand Rapids Mich. Composition Mustard and turpentine oils camphor and menthol alcohol (63.2 per cent) and water For hay fever asthma etc. Fraudulent therapeutic claims.—[N J 17846 June 1931]

Aceo Balm.—A. C. Clark & Co. Inc. Brattleboro Vt. Composition Ointment with petrolatum base containing zinc oxide boric acid and a trace of pine needle oil For antiseptic uses Fraudulent therapeutic claims.—[N J 17847 June 1931]

Bering Ear Oil.—Henry Heide and Sons, St. Paul Minn. Composition Essentially a bland oil with a small amount of methyl salicylate For ear troubles. Fraudulent therapeutic claims.—[N J 17850 June 1931]

Dr. Pusheck's Cold Push.—Pusheck Health Laboratories Chicago. Composition Acetanilid (15 grains per tablet) camphor and small amounts of quinine coated with iron oxide and starch For fevers influenza etc. Fraudulent therapeutic claims.—[N J 17851 June 1931]

Kelp Ine.—Kelp Ine Products Corporation of America Seattle Composition Essentially a potassium soap without iodine and iodides For skin infections etc. Fraudulent therapeutic claims.—[N J 17852 June 1931]

Terpedo Volatex.—W. C. Belmonte New York. Composition Volatile oils including menthol camphor and eucalyptol For nasal and throat troubles. Fraudulent therapeutic claims.—[N J 17853 June 1931]

Hydes Rheumatol and Kidney Remedy.—Hyde Remedy Co. Meridian Miss. Composition Sodium salicylate potassium iodide citrates alcohol (3.85 per cent) sugar and water For rheumatism and kidney diseases. Fraudulent therapeutic claims.—[N J 17856 June 1931]

Cuticura Pills.—Potter Drug and Chemical Corp. Malden Mass. Composition Quinine sulphate iron carbonate red pepper nuxvomica alkaloids iodides and aloin For indigestion etc. Fraudulent therapeutic claims.—[N J 17858 June 1931]

Amogen Tablets.—Amogen Co. San Antonio Texas Composition Calmel and extracts of plant drugs including a laxative drug and a mydriatic. General cure-all. Fraudulent therapeutic claims.—[N J 17859 June 1931]

Coloni Compound—Coloni Laboratories St Louis Mo Composition Extracts of plant drugs including valerian with alcohol (17.6 per cent) glycerin and water For female weakness etc. Fraudulent therapeutic claims.—[N J 17861 June 1931]

Radumac—Radumac Mineral Co Los Angeles Composition Water solution of the sulphates of aluminum iron calcium magnesium and sodium with sulphuric acid General cure all Fraudulent therapeutic claims.—[N J 17862 June 1931]

Garrett's Constitutional Virginia Dare Wine Tonic—Fruit Industries Ltd New York Composition The red variety contained alcohol (over 22 per cent) sodium glycerophosphate, nitrogenous matter a bitter a reducing sugar and water The white variety contained the same ingredients but in slightly different proportions For tonic purposes Fraudulent therapeutic claims.—[N J 17863 June 1931]

Chloro Zol—American Drug & Chemical Co Minneapolis Composition Chloramine. For sore throat pyorrhea female troubles etc Fraudulent therapeutic claims.—[N J 17864 June 1931]

Tettremidy—Eucaline Medicine Co Dallas Texas Composition Acetic acid glycerin and water dyed pink For skin diseases Fraudulent therapeutic claims.—[N J 17865 June 1931]

Dr Whitehall's Rheumatic Remedy—McCullough Drug Co Cincinnati Ohio Composition Acetanilid sodium salicylate sugar starch and tale For rheumatism etc Fraudulent therapeutic claims.—[V J 17866 June 1931]

Athlophoros Searles Remedy for Rheumatism—Athlophoros Co Pom fret Center Conn Composition Sodium salicylate, volatile oils including cassia and peppermint with methyl salicylate glycerin and water For rheumatism etc. Fraudulent therapeutic claims.—[V J 17869 June 1931]

Allen's Ulcerine Salve—J P Allen Medicine Co St Paul Minn Composition Essentially a lead soap and linseed oil For ulcers etc Fraudulent therapeutic claims.—[N J 17870 June 1931]

Marshall's Prepared Cubebs Cigarettes—James B Horner Inc New York Composition Essentially powdered stem and fruit tissue of cubebs For asthma etc Fraudulent therapeutic claims.—[N J 17873 June 1931]

Prescription No 3913—C H Platt New York Composition Potassium iodide colchicine extracts of plant drugs including sarsaparilla with alcohol sugar and water flavored with sassafras oil For rheumatism etc Fraudulent therapeutic claims.—[N J 17903 June 1931]

Ru Co—Clyde Collins Chemical Co Inc Memphis Composition Essentially epsom salt Glauber's salt and small quantities of saccharin citric acid and tartaric acid For rheumatism etc Fraudulent therapeutic claims.—[N J 17905 June 1931]

Grimalt's Syrup of Hypophosphite of Lime—E Fougere & Company Inc New York Composition Essentially calcium hypophosphite morphine hydrochloride ($\frac{1}{16}$ grain per fluid ounce) sugar and water For pulmonary troubles etc Fraudulent therapeutic claims.—[N J 17904 June 1931]

Hubbel's Formula—Hubbel Products Corporation Boston Composition Essentially alcohol (57.6 per cent) chloral hydrate volatile oils including camphor eucalyptol and clove oil with formaldehyde acetic and sulphuric acids small quantities of extracts of plant drugs and water For pyorrhea etc. Fraudulent therapeutic claims.—[N J 17905 June 1931]

Jenkins Rheumatic Remedy—J W Jenkins Youngstown Ohio Composition Essentially salicylic acid potassium iodide small quantities of extracts of plant drugs glycerin alcohol sugar and water flavored with sassafras oil For rheumatism etc Fraudulent therapeutic claims.—[N J 17906 June 1931]

McCormick's Freosine Salve—McCormick & Co Baltimore Composition Ointment with a petrolatum base containing menthol camphor eucalyptus and cinnamon oils For pneumonia etc Fraudulent therapeutic claims.—[N J 17908 June 1931]

Galpin's Antiseptic Vaginal Suppositories—H T Galpin Inc Amityville N Y Composition Essentially boric acid a quinine compound and ammonia alum in a base of cocoa butter For female disorders Fraudulent therapeutic claims.—[N J 17914 June 1931]

Wampole's Extracto de Hígado de Bacalao (Wampole's Cod Liver Extract)—Henry K. Wampole & Co Inc Philadelphia Composition Cod liver extract wild cherry malt extract (diastatic) hypophosphites of calcium sodium potassium manganese iron pyrophosphate sulphates of quinine and strychnine with aromatics General cure all Fraudulent therapeutic claims.—[N J 17915 June 1931]

Ducro's Alimentary Elixir—Aglesias & Co Inc New York Composition Essentially meat extract sugar alcohol (18 per cent) and water For nervous troubles etc Fraudulent therapeutic claims.—[N J 17916 June 1931]

Hydroleins—Century National Chemical Co Paterson N J Composition Cod liver oil salicylic acid alcohol pancreatin and water For consumption rheumatism etc Fraudulent therapeutic claims.—[N J 17920 June 1931]

Jarabe Fenleo—Caribou Laboratories Aguadilla Puerto Rico Composition Essentially carbolic acid glycerin sugar and water For asthma etc Fraudulent therapeutic claims.—[N J 17925 June 1931]

Jarabe Hipofosfito de Cal—Caribou Laboratories Aguadilla Puerto Rico Composition Essentially calcium hypophosphite sugar and water For nervous troubles etc Fraudulent therapeutic claims.—[N J 17923 June 1931]

Lanman & Kamps Pure Cod Liver Oil and Cod Oil Black—Lanman & Kemp Inc New York Composition The Pure Cod Liver Oil consisted simply of cod liver oil the Cod Oil Black consisted of rancid dark-colored cod liver oil For consumption rheumatism etc. Fraudulent therapeutic claims.—[V J 17924 June 1931]

Viala Phenle Syrup—Charles L Hunsing & Co New York Composition Carbolic acid morphine hydrochloride (0.072 grain per fluid ounce) sugar and water For bronchial trouble etc. Fraudulent therapeutic claims.—[N J 17925 June 1931]

Crao Terplina Wampole—Aglesias & Co Inc New York Composition Essentially creosote terpin hydrate glycerophosphates a trace of chloroform alcohol and water For bronchial troubles etc. Fraudulent therapeutic claims.—[N J 17929 June 1931]

Bentonia—Bentonia Co Albuquerque N M Composition Insoluble matter (clay) with extracts of plant drugs including buchu a laxative drug a bitter drug and glycerin alcohol and water peppermint flavored General cure all Fraudulent therapeutic claims.—[V J 17931 June 1931]

Ampoules Galsarsine Ducatte—E Fougere & Co New York Composition Essentially guaiacol cacodylic acid strychnine sulphate and water For laryngitis. Fraudulent therapeutic claims.—[V J 17932 June 1931]

Pactil Colberg—Drug Co of Puerto Rico Inc San Juan Puerto Rico Composition Essentially codeine phosphate creosote compounds of sodium and potassium bromides glycerophosphates citrates sugar and water For bronchial troubles etc. Fraudulent therapeutic claims.—[N J 17935 June 1931]

Correspondence

'HOW TO BUDGET HEALTH'

To the Editor—Several misstatements appear in the review of 'How to Budget Health' in THE JOURNAL, April 1

The reviewer says that the methods used to recruit members [of medical guilds] are by paid advertisements by direct mail promotion and by personal solicitation—methods that are contrary to recognized ethical ideas

I specifically opposed the use of paid advertisements in promoting medical guilds This form of promotion the book states, 'is most vulnerable on ethical grounds and should probably not be resorted to' (p 194) The only direct mail promotion advocated is in the form of announcements sent to their patients by doctors who join the staff of a guild, or announcements of the adoption of the guild plan by an existing medical institution (p 195) As for personal solicitation the only kind advocated in the book is by the word of mouth of satisfied patrons' who would naturally, without any stimulation by the officers of the guild tell their friends about it (p 195)

The reviewer says It is stated that these guilds would not be able to meet expenses and that it would be necessary to have some kind philanthropist subsidize the guilds in order that they may be able to pay the running expenses As a matter of fact the whole argument of the book is in favor of complete self-support

It is stated that the membership fees should be set at a conservative figure which would meet all expected operating and overhead costs (p 223) and again The guild is to be completely self-supporting (p 225) It was recognized however, that in order to insure the members of a guild staff against loss it would be necessary to have an adequate financial guaranty of continuous operation for at least three and possibly five years (p 223) A guaranty which might never be called for is different from a 'subsidy' which implies continued assistance

Finally, your reviewer states that 'Mr Clark says that it [the guild plan] was found to be illegal in New York State' and that 'the scheme would probably come under the laws governing insurance agencies' The text of the book is in direct contradiction to these assertions Chapter 7 demonstrates in detail that medical guilds would be legal in New York State under the membership corporations law if organized as hospital corporations or 'partnerships' (p 194) It is furthermore pointed out in the same chapter that medical

guilds set up in the state of New York would not be considered insurance agencies. They would not, therefore, be subject to the jurisdiction of the insurance laws and the agencies set up to administer them' (p 187)

EVANS CLARK New York.
Director, Twentieth Century Fund, Inc.

PERMANENT ENLARGEMENT OF THE LIPS AND FACE

To the Editor—Some comments seem to be needed on the paper 'Permanent Enlargement of the Lips and Face Secondary to Recurring Swellings and Associated with Facial Paralysis A Clinical Entity,' by New and Kirch (*THE JOURNAL*, April 22, p 1230). The authors say that "The condition is apparently a clinical entity, but we have been able to find only slight mention of it in the literature."

The condition is a clinical entity which has been recognized for fifty years and repeatedly described. It was first described by Jonathan Hutchinson in the *Medical Times and Gazette* (14, 1883). It was again considered by him in the *Illustrated Medical News* (Oct 20, 1888, p 82) and in the *Archives of Surgery*, London (4, plate LXVI, 1893). It has also been described by Weaver and Tunncliffe (*J Infect Dis* 5:569 [Dec. 18] 1908), by Bourgeois and Egger (*Rev hebdomadaire*, May 22 1909, p 611), by Adam (*Brit M J* 2:933 [Oct. 2] 1909), in Fox, Allbutt and Rolleston's *System* (1911, vol IX, p 183) by Mackenzie (*Brit J Dermat* 8:138, 1896), by Foster (*J Cutan Dis* 27:72, 1909), by Pollitzer (*ibid*, p 176) and by me (*Arch f Dermat u Syph* 111:41, 1912). It is commonly referred to briefly in current works on dermatology. Sutton, MacLeod and Ormsby in their textbooks—the first three that I took up—all refer to it. Ormsby gives it a brief but adequate consideration as an independent clinical entity in the group of erysipelas-like infections.

Solid edema of face (From Hutchinson's Archives of Surgery)

The pictures given in the New and Kirch article are typical of the illustrations that appear in various accounts of the condition. This is well shown by the illustration from Hutchinson's *Archives of Surgery*, reproduced herewith, which was published forty years ago. Hutchinson's comment on these two cases was as follows:

This plate shows the portraits of two women who were the subjects of that form of solid oedema which not unfrequently occurs as a result of repeated attacks of an erysipelas swelling of the face.

I have published on different occasions a considerable number of examples of this malady. The usual history is that the patient has been liable for years to recurring attacks of erysipelas transitory in duration and limited to the face but attended with very considerable oedema. The final condition is one allied to Elephantiasis. The disease is wholly local.

That is still essentially the whole story. The condition is not excessively rare in dermatologic practice. I find eight cases in my private records and have certainly seen as many more. I have seen a new case within two weeks. From my cases duplicates could be selected of almost every case that New and Kirch illustrated.

Solid edema of face. (From Hutchinson's Archives of Surgery)

They say that "the question of lymphangitis or recurring erysipelas can be excluded." How, they do not explain. They briefly refer to their biopsies, saying "Nothing was found other than edematous tissue containing lymphocytes. After the patient had received repeated treatments, biopsy disclosed fibrous and inflammatory changes in the tissues, as would be expected." Others have found these fibrous and inflammatory changes as they expected in cases which have not been treated, and they are the sort of histologic changes that occur with chronic cellulitis.

From the days of Hutchinson's original description to the present, the condition has been associated in the minds of observers with recurrent attacks of erysipelas or lymphangitis, which caused lymphatic obstruction and secondary proliferation of fibrous tissue, exactly analogous to the process that occurs in elephantiasis. Many authors, in fact, consider it under elephantiasis. Sutton, for example refers only to elephantiasis of the face and gives an illustration of elephantiasis of the upper lip which is a characteristic picture of the condition affecting the lip.

My first case was in a Negro boy and, as would be expected from the notorious tendency of Negroes to connective tissue overgrowth, was an extreme example involving the whole face. In him it was associated with recurrent attacks for many years of frank erysipelas with the systemic and local characteristic symptoms of erysipelas. This is frequently so. For many years I thought the condition was usually associated with frank outbreaks of lymphangitis or cellulitis. Several of my later cases, however, have given no history of typical attacks of erysipelas but have simply had recurrent attacks of swelling. This, of course, does not exclude either lymphangitis or cellulitis of the cheek. In the soft tissues of the lips and cheeks an inflammatory reaction can occur which is manifested only by swelling. I have within a week seen a cellulitis of the cheek without elevation of temperature, pain or even any redness,

simply a dense swelling of the deep structures of the cheek, which runs an acute course and quickly subsides

MacLeod, in fact, describes this condition under "recurrent erysipelas without constitutional symptoms," which may occur 'where the tissues are lax, as about the eyelids,' and shows as 'a definite swelling in which the redness is comparatively little marked, hence the name white erysipelas (Unna)'

Cases which have been examined histologically bear out this interpretation of the condition

New and Kirch do call attention to an important new complication that is facial paralysis I have not recently thoroughly reviewed the literature, but as far as my memory goes that has not hitherto been recorded as a complication For it they offer no explanation It would seem to be explainable as a possible complication of chronic inflammatory process invading a nerve traversing the tissues in which this process occurs and producing sufficient destruction of nerve tissue to cause interference with function

New and Kirch report that the results of treatment of the condition have been satisfactory Adam has reported two cases in which the result of antiseptic treatment has been cure, and others, with treatment based on the same principle, have occasionally reported successful results In the experience of most observers, treatment has been unsatisfactory As a rule after the enlargement of the tissues has been established for a considerable time, treatment has not been satisfactory In this the analogy to elephantiasis is exact

WILLIAM ALLEN PUSEY, M D, Chicago

NEPHROPEXY

To the Editor—In THE JOURNAL, April 15, page 1167, is an article entitled "Nephropexy by Means of a Fascial Hammock," by David R. Melen, M D, of Rochester, N Y This procedure is reported as a new method of accomplishing nephropexy In the *Urologic and Cutaneous Review* (34 679 [Oct.] 1930) was published my article on 'Nephropexy by Fascial Transplant,' in which I reported several cases of fascia lata as a hammock suspended from the twelfth rib My patients were relieved of symptoms and the later roentgenograms showed good position of the kidney Dr Melen used a slightly different technic in attaching the fascia to the kidney, but the method is essentially the same as mine

CLARENCE EMERSON, M D, Lincoln Neb

[This letter was referred to Dr Melen, who replies as follows]

To the Editor—I looked up the article mentioned. It is a fine method. I overlooked it in my references

I am not in favor of the use of autofascia from the patient's thigh, as it makes an additional operation, and the fascia is absorbable.

I like the animal fascia better as it is nonabsorbable.

I am not in favor of cutting the intercostal muscle free from the twelfth rib, as it is time consuming is unnecessary, and adds the risk of accidental pneumothorax in cases in which the pleura extends lower than normal

Dr Emerson's method preceded mine It is not his fault that I did not know about it, and he should be given credit for priority

I make no claim to newness or priority Dr O S Fowler used fascia as early as 1913, from the thigh, as Dr Emerson does (Fowler, O S Ureteral Obstruction Causing Urinary Stasis A New Etiology in Kidney Stones, with a New Method of Nephropexy to Secure Ideal Natural Drainage, THE JOURNAL, Jan 31, 1914, p 367) My method is different.

DAVID R MELEN, M D, Rochester, N Y

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address but these will be omitted on request.

ARSPHENAMINE IN NEUROSYPHILIS

To the Editor—What is the latest and most accepted theory relative to the lack of curative power of arsphenamine in neurosyphilis? Please omit name

M D New York

ANSWER.—The negative statement of this question would give the impression that arsphenamine has no curative powers in neurosyphilis Much must of course, depend on the aspect of neurosyphilis under consideration but it may be definitely stated that the arsphenamines do have curative powers in neurosyphilis and that unquestionably, as evidenced by the currently appearing clinical studies of the American Cooperative Clinical Group working with the United States Public Health Service in which early neurosyphilis at least is shown to be definitely responsive in a proportion of cases amounting approximately to 75 per cent of the whole to routine treatment with the arsphenamines and heavy metals The observations of Bruusgaard and of Ravaut are now being widely quoted as evidence that even the spontaneous evolution of a syphilitic infection leads to recovery from some degrees of neurosyphilitic involvement irrespective of treatment so that this factor must modify any overenthusiasm that might be expressed for the influence of the arsphenamines in standard practice The question has been repeatedly raised by serious students as to whether the arsphenamines have a positively injurious or predisposing effect on the course and development of neurosyphilis This question is extensively reviewed in most recent textbooks and reference may be had also to Guy's address before the Section on Dermatology and Syphilology (THE JOURNAL, Oct 4 1930 p 979) and a study by O'Leary and Rogin dealing particularly with this point (*Proc Staff Meet Mayo Clin* 7 273 [May 11] 1932) In general, it is now accepted that the adequate use of the arsphenamines in the treatment of syphilis does not predispose to neurosyphilitic involvement, though it is coincidentally powerless to prevent it in certain evidently predisposed cases The inadequate use of arsphenamines, on the other hand definitely predisposes to neurosyphilitic forms of relapse especially in early syphilis, and the same statement may be made though with less definiteness on patients treated with the arsphenamines without adequate support from the heavy metals, bismuth and mercury This type of relapse, known as neurorecurrence, was in the early days of arsphenamine treatment responsible for much of the prejudice that developed against the use of the drug because of its alleged tendency to precipitate neurosyphilitic accidents

In the treatment of late neurosyphilis other than dementia paralytica the good effect of the arsphenamines, given particularly in so-called tonic or moderate dosage, is now unquestioned Symptomatic relief from lightning pains in tabes, improvement in ataxia, and the rapid clearing up of many of the minor symptoms of cerebrospinal and tabetic neurosyphilis under arsphenamine therapy alone are now established beyond dispute. It has even been a question whether much of the effect of intraspinal therapy and of spinal drainage, now gradually losing popularity was not due to the beneficial therapeutic action of moderate doses of neoarsphenamine administered in preparation for the intrathecal injection of the arsphenaminized serum, or the drainage of the fluid

In dementia paralytica the arsphenamines are now recognized as virtually powerless Even under the most intensive form of administration they lead to only temporary improvement and short remissions, and no attempt should be made to substitute them except as purely preparatory treatment, for the vastly more effective arsenical trypanamide and for malarial therapy in properly selected cases In the clinically resistant gastric crises and primary optic atrophy the arsphenamines are not effective, and primary optic atrophy, of all the localized forms of neurosyphilis, has presented the strongest case against the use of this drug On the other hand the most recently reported results by More in the intraspinal therapy of primary optic atrophy again tend to support the belief in the effectiveness of this drug by a suitable route of administration

It must be recalled also that a certain amount of prejudice against the use of arsphenamines in neurosyphilis has undoubtedly arisen from the employment of too large doses without adequate heavy metal preparation in patients with acute neurosyphilitic processes The effect of such a misuse of these drugs

is to produce focal flare ups, frequently with disastrous consequences or damage, which is quite unnecessary when the technic of dosage and of preliminary heavy metal preparation, as described in recent textbooks, is properly understood

THE HEART TICKLER OR PACEMAKER

To the Editor—Can you give me any information concerning the heart tickler as developed by Dr. Albert S. Hyman? In the magazine *Time* it is described as an electric gold needle. I am physician for a coal mining company and was much interested in this article. If you can send to me any information concerning this or any other method used to revive the heart after it has received severe electrical shock I will greatly appreciate it.

A. R. CLAUSER, M.D., Madrid, N. M.

ANSWER.—The article that appeared in *Time* as well as in many newspapers was a popularized account of a report published in the *Archives of Internal Medicine* (50:283 [Aug.] 1932), on the resuscitation of the stopped heart by intracardial therapy, which described the experimental use of an artificial pacemaker. This paper, written by Dr. Albert S. Hyman, was one of a series of reports made in a six year study at the Witkin Foundation for the Study and Prevention of Heart Disease, Beth David Hospital, New York, concerning the problems associated with restoring automatic cardiac activity after standstill of the heart.

In a previous paper (*Arch. Int. Med.* 46:553 [Oct.] 1930) Dr. Hyman developed the theory that resuscitation of the stopped heart by intracardial injection was due entirely to the prick of the injected needle rather than to the pharmacodynamic action of the substance injected. The action of epinephrine, strophanthin, strychnine and eleven other substances in a series of animal experiments was shown to be secondary and of minor importance in restoring the normal cardiac cycle. Physiologic experiments demonstrated that for several minutes after complete cardiac arrest certain well established electrochemical phenomena are developed. As the myocardium becomes anoxic there is a rise in the acid component values of the delicately balanced ratio maintained in the normal electrolytic state of the heart muscle. This change is accompanied by increased irritability of all myocardial fibers as well as an increase in electrical conductivity of muscle segments. Any mechanical stimulus may at this time be sufficient to give rise to an ectopic focus for myocardial contraction, pinching, squeezing or thumping on the heart are age-old methods of resuscitation. The extrasystole that arises may be sufficient to initiate coronary circulatory movement with an immediate reduction of the altered chemical balance.

When intracardial injection is made, the prick of the needle serves to create an irritable point from which ectopic contractions are readily developed. The injured heart muscle immediately develops an action current, which temporarily assumes the role of the electrical activity of the pacemaker, so that an extrasystolic rhythm develops. When the injection has been made into the ventricles this extrasystolic arrhythmia may rapidly develop into a paroxysmal ventricular tachycardia and finally into ventricular fibrillation with cardiac arrest again.

Hyman pointed out that if the injection is made in the right auricle such types of arrhythmia will have a far less hazardous outcome, for paroxysmal auricular extrasystolic tachycardia, which subsequently becomes auricular fibrillation is not incompatible with life since the latter condition is a well known and easily managed clinical entity.

The theory and practicability of intra-auricular puncture of the stopped heart was discussed in the editorial columns of *THE JOURNAL*, May 30, 1931, page 1875 and subsequently in the correspondence columns of *THE JOURNAL*, July 11, 1931, page 124 and Aug. 8, 1931, page 408.

The recent contribution of Dr. Hyman and his associates at the Witkin Foundation, an abstract of which appeared in *THE JOURNAL*, Nov. 26, 1932, page 1887, has been the substitution of the needle prick theory in reactivating the stopped heart by an *electromechanical device* which simulates the pacemaker current. Instead of injecting the usual hollow needle into the right auricle of the heart, a special needle electrode containing an insulated conductor passing through the center of the needle shaft and terminating at the tip, is used. When this needle, which is the same size as the ordinary injecting needle is placed in the auricular musculature, a tiny electric current (about 1 millivolt) is sent through the needle and forms an irritable arc measuring about 1 mm in the myocardial muscle. This arc becomes an irritable point from which an ectopic beat is produced.

Since the number of electrical impulses can be controlled and since only one application of the needle is required, the automatic activity of the heart may be maintained by this ingenious apparatus which has been called the artificial pacemaker. With the ectopic beat arising in the auricle, the stimulus for con-

traction passes over the normal pathways of the heart and a normal cardiac cycle results. The apparatus itself is a spring motor controlled generator especially constructed to deliver a current of 1 millivolt at the needle point. The current is interrupted by a polyphasic rotating disk which permits 30, 60 or 120 beats per minute to be delivered. The device is a self-contained unit of simple construction and any physician who has had occasion to perform an intracardial injection for the restoration of the stopped heart will be able to use it without difficulty. The apparatus is manufactured by the Siemens-Halske (German General Electric) Corporation and will soon be ready for general distribution to hospitals and emergency stations throughout the country.

This method of resuscitating the stopped heart is especially valuable in those cases classified by Hyman as Group I, in which the heart, though normal, has been stopped by shock, electrocution or trauma. When the apparatus has been used soon enough, a favorable outcome has been found in more than half of the cases reported. So far as accidental electrocution is concerned, Hooker and his associates in Baltimore have shown that death occurs from ventricular fibrillation. If there has been no injury to the central nervous system, Hyman has demonstrated that cardiac arrest which follows such fibrillation may respond to stimuli from the artificial pacemaker.

ACTIVE IMMUNIZATION BEFORE TERMINATION OF PASSIVE IMMUNITY

To the Editor—I cannot agree with your answer to Dr. Daly (*THE JOURNAL*, January 21, p. 211) that there seems to be no good reason why active immunization should not be started before termination of the period of passive immunity. The free antitoxin of the injected diphtheria serum neutralizes part or all of the toxin contained in the toxin antitoxin or toxoid and so the forming of antibodies will be delayed or prevented. For the same reason a diphtheria patient who is treated with serum at the beginning of his illness can be cured and still have a positive Schick reaction so that he should be actively immunized after his illness (*Aldershoff Nederl. tijdschr. v. geneesk.* Oct. 27, 1928). For this reason I regard as justified the hunch of Dr. Daly that it may be immunologically unsound to proceed at once with active immunization against diphtheria before the termination of the period of passive immunization.

CORNELIS SCHAGEN, M.D., Oakland, Calif.

ANSWER.—As the question stated that it was desirable to obtain an active immunization as soon as possible owing to the local prevalence of the disease, the answer was formulated with the needs of the practical situation in mind. Now, passive immunity begins to fall off at once after the injection of the antitoxic serum. It grows less effective day by day. As ordinarily induced it is said to last only for three or four weeks. There is no way of telling precisely when it no longer is protective, or detectable except by repeated Schick tests. To begin active immunization before the termination of the passive immunity will not do any harm, it might be of benefit in starting active immune reactions just as soon as the passive immunity no longer protects. From the practical point of view there is nothing immunologically unsound in beginning active immunization before the termination of passive immunity.

X-RAY TECHNIC IN ACNE VULGARIS

To the Editor—Please give me the best x-ray technic for treating acne vulgaris.

L. A. CROWELL, M.D., Lincoln, N. C.

ANSWER.—Unfiltered x-rays, one-fourth skin unit (about 80 roentgens) each week. For the face, the treatment should be applied to each side of the face. It should not be applied to the front of the face. If the disease affects the chest and back, treatment may be applied to these parts. If so, the face must be protected while the chest is being treated, and vice versa. The maximum number of treatments is sixteen. All the details of this technic with indications and contraindications are contained in MacKee's book "X-Rays and Radium in the Treatment of Diseases of the Skin" Philadelphia, Lee & Febiger, 1927.

SALTY TASTE IN YOUTH OF DIABETIC PATIENT

To the Editor—I have under my care a patient who has mild diabetes with a hypertension controlled with a low carbohydrate diet. She does not use insulin and is sugar free in 75 per cent of the specimens. She has a salty taste in her mouth which is persistent. I would appreciate help with this problem. Please omit name.

M.D., Connecticut

ANSWER.—It is possible that the salty taste is not due in any way either to the disease or to the diet. One would want to be sure that there was no pathologic condition in the throat, accessory sinuses of the nose, or the teeth, also, that no medicine is being given. If nothing is found in these investigations it might be wise to ascertain the nature of the gastric secretion.

FISTULA IN ANO IN TUBERCULOSIS

To the Editor—1 Is the following diagnosis justifiable? 2 What is the latest opinion regarding tuberculosis being the cause of fistulae in ano? Section shows smooth muscle and fibrous connective tissue with a small piece of squamous epithelium attached. A few mucous glands are found. The tissue shows many foci of lymphocytes and endothelial cells with an occasional giant cell of the Langhans type. One focal area shows lymphocyte and endothelial cells in the periphery with a giant cell in the center. Acid fast stains do not reveal any acid fast bacilli. The diagnosis was tuberculosis of rectal fistula. 3 Will you also give me your opinion about the following: I sometimes see a selective pulmonary collapse that is the collapse of a lobe of a lung which is explained by the plugging with mucus of the bronchus leading to this lobe. The roentgenogram shows pneumothorax with selective collapse. Massive collapse of the lung following abdominal surgery is attributed to the same cause. The roentgenogram does not show true collapse in the same sense but it shows airless lung shall we say atelectasis and the entire lung field is blotted out. In view of the foregoing is it feasible to give the same explanation to the two pictures? For example if the upper lobe of one lung is found plastered against the mediastinum can this be explained by plugging of the bronchus supplying this lobe? If so how has the relative negative pressure inside the pleural cavity been reduced to allow collapse of this lobe without the collapse of the remainder of the lung? If it is explained by absorption of the air in the alveoli why does not the postoperative massive collapse give the picture of a pneumothorax instead of that of airless lung (or atelectasis)? Please omit name.

M D Louisiana

ANSWER—1 Yes, the diagnosis is most probably correct. The cellular complex is entirely compatible with tuberculosis. Acid fast bacilli are sometimes difficult to find in such lesions.

2 Fistula in ano in tuberculous individuals is almost always a tuberculous process. Various investigators have found definite evidence of tuberculous pathologic change in over 75 per cent of such specimens, when serial sections have been made and carefully studied (Fansler, W A *Journal-Lancet* 47:269 [June 15] 1927; Martin, C L, Chicago Municipal Tuberculosis Sanitarium). No doubt all but a trivial minority of the other 25 per cent are also tuberculous, either primarily or secondarily infested with tubercle bacilli. There is no reason, however, why a nonspecific anal lesion may not occur in tuberculous subjects but the opinion and evidence at present, seem to indicate that practically all anal fistulas in tuberculous persons are tuberculous or ultimately become tuberculous. In nontuberculous persons, or in persons without active tuberculous disease, however most anal fistulas are considered nontuberculous. Figures from the Mayo Clinic and other reliable authorities give only about 3 to 5 per cent tuberculosis in such cases. There are many chemical, bacterial and mechanical injuries that may involve this vulnerable part of the anatomy which are definitely not tuberculous. Although it has not been demonstrated it is conceivable that all anal fistulas may be nonspecific at the beginning, but in tuberculous individuals they become secondarily infected by the constant stream of tubercle bacilli that pass over them. The incidence of such fistulas is about 3 to 7 per cent of tuberculous persons, while the nontuberculous persons have about a hundred times less. A point of difference may be that in the nontuberculous, many small early lesions heal. Only the large lesions persist and become infected with nonspecific bacteria, while in the illnourished tuberculous patient the small early lesions soon become tuberculous, after which they heal with difficulty, if ever.

3 The questions on lung collapse are much more involved. The cases mentioned cannot be considered at all as parallel phenomena. Some are rather well understood and others little. The first type of collapse spoken of seems to be the best understood, i.e. the kind so frequently encountered in tuberculosis or following influenzal pneumonia. It is found most frequently in the right upper lobe. Here there is an antecedent pathologic process that involves a certain pulmonary region, causing the closure of a main stem bronchus perhaps by tenacious mucus, which may (in tuberculosis) rapidly become fibrocaseous. The pulmonary tissue then become airless, leaving a partially collapsed lobe with irregular areas of involvement by the disease. Soon the intervening collapsed tissue becomes soggy with serofibrinous exudate, to be followed by an invasion of monocytes, lymphocytes fibroblasts and finally, fibrosis. Within a period of from four to six months this fibrous tissue contracts, 'plastering' the lobe against the mediastinum. Now, a pneumothorax early in this process will greatly speed it up and produce selective collapse at its best. It is not all collapse however but partially contraction.

This is no doubt the condition that Leon Bernard (Les débuts et les arrêts de la tuberculose pulmonaire Paris Masson & Cie, 1932) has called 'lobite'. In spite of the fact that Bernard reports a favorable prognosis in nearly all these cases, they may and frequently do caseate excavate and spread.

It is not to be taken for granted however that all selective collapse can be explained on this basis. There is no reason

why it may not occur from the same causes as massive collapse, an entirely different and poorly understood clinical entity.

The first complete study of massive collapse was made by William Pasteur in 1890 (*Internat J M Sc* 100:242 1890) and on irregularly to his last report in 1914, first on diphtheria paralysis, then on operative cases. Pasteur was the first to suggest an active massive collapse 'in contradistinction to passive collapse. By active collapse' he meant a failure of active respiratory power, in contradistinction to the plugging of a bronchus. Since then a large number of authors have experimented and theorized about the matter, till at present the information may be summarized about as follows. Obstruction of a lobe bronchus by a complete obstruction (artificial plug or tenacious mucus) will lead to a complete collapse, owing to solution of the trapped air into the blood stream, if the blood stream remains intact (Lichtheim, *L Arch f exper Path u Pharmacol* 10:54, 1878, 1879). The collapse is centripetal from the obstruction and is not complete in lobular obstruction because of the intercommunication of Kohnsche pores (Van Allen, C M and Adams, W E *Surg Gynec & Obst* 50:385 [Feb] 1930). In human disease the cause is thought to be tenacious mucus. This mucus plug theory has been supported by Elliott and Dingley (*Lancet* 1:1305, 1914), Jackson and Lee (*Tr Am S A* 43:723, 1925), Coryllos and Birnbaum (*Arch Surg* 16:501 [Feb] 1928) and others, but some facts cannot be explained on this basis alone because Pasteur and Rose Bradford (*Quart J Med* 12:127 [Oct] 1918) have reported postmortem examinations in which no such plugs were ever found. The latter asserts also that in many patients there is no clinical evidence of them. Furthermore, massive collapse is most often sudden, while the plugged bronchus leads to a gradual collapse. Another theory is that there is a reflex spasm of the bronchioles as in asthma (Bradford *Quart J Med Sante*, L R *Radiology* 4:221 [March] 1925, and others). Sante reasoned that there must be something in addition to simple collapse because a pneumothorax lung is transparent on roentgen examination, while the collapsed lung is solid. It must be realized, however that the 'artificial' pneumothorax lung is never entirely airless, while the other usually is. A spontaneous pneumothorax lung, notwithstanding, may be airless. Another theory proposes (Briscoe *J C Quart J Med* 13:293 [April] 1920) a weakening of the diaphragm by inflammation another attributes it to poor posture. But none explain all the phenomena. J M W Morison of Edinburgh suggests that one must look on the lungs as a dynamic muscular organ as described by C C Macklin (*Physiol Rev* 9:1 [Jan] 1929) functioning rhythmically in peristaltic-like waves in expiration. The action is regulated by the sympathetic and vagus nerves—the former to relax, the latter to contract. (A precedent for such a spastic condition is afforded in asthma.) An interference with the vagus would overrelax the bronchi permitting an accumulation of mucus (which may be dry or become sticky in a dehydrated person). As the sympathetic stimulation wears off, the vagus may again reassert itself and cause spasm—and a completion of the collapse.

Irrespective of the merits of this theory, it is the only one proposed that will explain all the facts. There seems little doubt now that there may be two types of massive collapse as suggested first by Pasteur an active and a passive. Recently the whole field of collapse has been ably treated by Ernest Fletcher (*Tubercle* 14:3 [Oct] 1932). This author confines atelectasis to the unexpanded lungs of infants—the lobar and lobular—sometimes leading to congenital bronchiectasis and cystic lung respectively apneumatosi to the simple airless lung due to simple plugging of a bronchus comparable to 'passive collapse' atelectasis (a new term) involving the sudden massive 'active' collapse and the slow type due to diseased lung tissue, and finally, pneumothorax.

MAZOPLASIA WITH PAINFUL ENGORGEMENT
OF BREASTS

To the Editor—I have a patient aged 37 the mother of two normal children who were nursed during infancy. The patient weighs 150 pounds (68 Kg) and is 5 feet 6 inches (167 cm) in height. She complains of pains and engorgement of both breasts with no relationship to the menses these symptoms persisting sometimes for a month at a time. An examination of the breasts reveals that they are normal with regard to masses there is no increased tenderness and the nipples are normal. The patient is not pregnant her youngest child is 12 years of age. Kindly advise probable diagnosis and treatment. Please omit name. M D, Illinois.

ANSWER—The condition described is a physiologic one to which Sir Lenthal Cheate has given the name 'mazo-plasia'. The breasts enlarge because of a hyperplasia of the epithelial and connective tissue elements. There is desquamation of epithelial cells in the ducts and acini accompanied by hyper-

plasia of the pericanalicular and periacinous connective tissue, and frequently also new acini are formed. The epithelium that is shed accumulates in and distends the ducts and acini, producing generalized pain and often nodules throughout the breast.

In the normally menstruating women, changes are constantly taking place in the breasts as the result of stimulation by hormones circulating in the blood. Most women do not recognize any unusual changes associated with the menses, but some complain of pain and tenderness in one or both breasts. Frequently an enlargement of the breasts is observed. In typical cases the pain begins from ten to fifteen days before the menstrual flow and diminishes or disappears when the flow of blood begins. In some cases as the one cited in the query, the pain is not associated with the menstrual cycle, and it is generally more pronounced in one breast than in the other. The breasts are usually somewhat tender and the glands feel more solid than usual.

Cutler (THE JOURNAL, April 11 1931, p 1201) has thoroughly discussed the question of painful breasts and recommends ovarian residue to overcome the pain. This therapy is based on the belief that painful breast are associated with excessive formation of corpus luteum. The administration of ovarian residue apparently tends to cause a cessation of the abnormal epithelial and connective tissue hyperplasia by counteracting the excessive corpus luteum secretion thus diminishing or removing its influence on the breasts. In a certain number of women after the use of ovarian residue the breasts soften and the painful nodules disappear. Cutler suggests that patients be given 5 grains (0.3 Gm) of ovarian residue three times a day, beginning fifteen days before the menstrual period starts and continue taking this amount until the flow begins. Women who are not benefited much by this dosage should take an additional 5 grains daily beginning with the menstrual flow and continuing until fifteen days before the next expected flow, from which time they again take 15 grains daily. If the menstrual flow becomes excessive, the amount of ovarian residue should be reduced.

NO GONORRHEAL URETHRAL DISCHARGE

To the Editor—I have a patient a man aged 29 who ten years ago had a painless urethral discharge. He consulted a physician who examined a smear and told him it was not gonorrhea and to forget about it. The discharge ceased in about two weeks. Three years ago after an interval of seven years he commenced again to have discharge although very small in amount. He has consulted a number of physicians who have examined his prostate and have taken smears and they all told him they did not know what it was due to. My examination revealed a normal sized gland with a normal feel to the touch and a small amount of fluid was expressed on massage. A smear showed over 20 pus cells per high power field but no organisms. The patient insists on knowing the cause of his infection. Can you state an opinion? Also can you advise any treatment besides prostatic massage which he is getting at present which will help clear up the infection? Please omit name.

M D Massachusetts.

ANSWER.—An aseptic purulent discharge from the urethra is as a rule secondary to chronic congestion of the prostate and seminal vesicles. It is often difficult to trace the original cause of these conditions. In some instances this syndrome in the male corresponds to endocervicitis in the female partner brought about by the use of occlusive pessaries especially if they are made out of rubber. Irrigations of the anterior urethra as a rule aggravate the condition. The application of medical diathermy to the penile urethra and prostate and seminal vesicles is quite successful. Massage at intervals of the prostate and seminal vesicles is also indicated. It has to be kept in mind that successful evacuation of the seminal vesicles can be accomplished only by the use of a club-shaped instrument constructed for this purpose.

CORRECTIVE MEASURES IN CROSS EYES

To the Editor—I should like to have your opinion as to how soon corrective measures should be started on a child's eyes that do not sometimes focus properly. This child is 13 months old and it is only in the past two weeks that the condition has been noticeable. At times the accommodation seems quite normal but at other times she may look definitely crossed eyed. I should also like to know what can be done. Please omit name.

M D Illinois

ANSWER.—Not infrequently are children under the age of 12 months more or less cross-eyed principally because central visual acuity has not yet been developed to the full extent and because fusion has not yet taken place. In the majority of such cases, parallelism develops spontaneously and attention is not required. But if the strabismus persists, the child should receive ophthalmologic attention as soon as possible. Refraction under full atropine cycloplegia should be performed and the existing errors of refraction corrected. If the vision is

manifestly lower in one eye than the other, part time occlusion of the good eye should be practiced. As soon as the child is able to cooperate, orthoptic training exercises should be started with the aim of developing fusion as early as possible. In resistant cases it is the practice of today to operate between the age of 3 and 5 years, provided at least eighteen months orthoptic training has shown that the strabismus cannot be corrected by nonsurgical means.

ILLUMINATING GAS AND ABORTION

To the Editor—A woman aged 30 who has had two normal pregnancies the last one being four years ago became pregnant in July 1932. During her first trimester she complained of malaise and indefinite complaints, such as headaches, nervousness and mild gastro-intestinal symptoms which were quite different from those present in the average case of pregnancy. The physical and laboratory results were negative. In October 1932 she had a spontaneous abortion from which she recovered without complications except for the continuance of the indefinite complaints mentioned. It later developed that during her entire period of pregnancy she was living in a house in which there was a rotted gas pipe and that she and her family were exposed to the inhalation of undetermined amounts of illuminating gas. Her husband who gave a history of chronic peptic ulcers was also affected by the return of his gastric symptoms more or less continued during his occupancy of this dwelling. I should like to know the possible effect of inhalation of small quantities of illuminating gas over a period of three months on the course of pregnancy, the possibility of its being the cause of the miscarriage and its effect on a patient with chronic peptic ulcers. Could a child of 6 living in the same house entirely escape from the effects of the gas while the adults became affected? Please omit name and address. I would appreciate inclusion of references.

M D Missouri

ANSWER.—The inhalation of illuminating gas over a long period of time sufficient to produce a certain degree of poisoning can lead to an abortion. Williams (Obstetrics, ed 6 1930 p 762) in discussing the etiology of abortion, says that "poisoning with phosphorus, lead, illuminating gas and other substances may lead to similar results" (death of the fetus and its subsequent expulsion from the uterus). De Lee (Obstetrics ed 5 1928, p 451) in his discussion on the maternal causes of abortion, says that the sudden rise of temperature may stimulate the uterus to action as also may the hypercarbonization of the blood in those diseases which are attended by cyanosis. Stockard (Am J Anat 28 115 [Jan] 1921) found that a temporary reduction in the oxygen supply of the environment may lead to death of the embryo.

Illuminating gas is poisonous chiefly because of the carbon monoxide which it contains and the most frequent source of carbon monoxide poisoning is illuminating gas, which contains from 4 to 16 per cent of carbon monoxide in coal gas and from 30 to 40 per cent in water gas. Usually there is a certain degree of safety in the odor of illuminating gas, but a leaky gas main may be the source of the gas, which may lose its odor by filtration through the ground and find its way into apartments some distance from the source of the leak.

Carbon monoxide has a pronounced affinity for the hemoglobin of the blood displacing molecule for molecule the oxygen which is combined in the form of oxyhemoglobin, thus preventing the normal oxygen-carrying power of the blood and causing the tissues to suffer for want of oxygen (anoxemia).

Webster (Legal Medicine and Toxicology, 1930, p 550), in a comprehensive article on this subject says "In the home the sources of CO are many and are ordinarily disregarded by most individuals. Many of us are constantly subjected to the possibility of absorbing carbon monoxide which may arise from leaky gas fittings, incomplete combustion of carbonaceous matter in stoves, grates, furnaces, leaky rubber tubing used to connect gas heaters, etc."

The symptoms of chronic poisoning from illuminating gas vary with the time of exposure and the degree of concentration. They include progressive fatigue, muscular weakness, headache, dullness and mental depression, disturbed vision, a peculiar transient ashy pallor which may change to a more or less greenish pallor, red patches on the cheek bones, palpitation of the heart, nausea, vomiting, vertigo, slowing of the pulse and dyspnea.

From the foregoing statements it appears that both the miscarriage in the wife and the return of the gastric symptoms in the husband may readily have been due to chronic poisoning from illuminating gas. The escape of the child from the effects of the gas is not easy to explain unless the child spent the greater part of each day in the open air outside the home and therefore was not exposed much to the gas. Henderson and Haggard (Noxious Gases 1907 p 106) say "When two individuals one of whom is much larger than the other, or when an adult and a child, both at rest are exposed to the same atmosphere, it is the smaller and younger individual with the more active metabolism who absorbs carbon monoxide and

tends to approach saturation the more rapidly Small individuals therefore succumb to carbon monoxide more rapidly than large individuals for the volume of their respiration is greater in relation to their volume of blood? Webster says

While there is little difference in susceptibility of the two sexes to the action of such gases as carbon monoxide, yet the female, being somewhat more accustomed to breathe the vitiated air of the house, has possibly a slightly greater resistance to its action"

PSYLLIUM SEED—LIQUID PETROLATUM—SEDATIVES IN HEART DISEASE

To the Editor—1 Recently to reply to an inquiry you spoke of Psylla as an irritant I thought it was taken only as added bulk. What becomes of the mucilaginous covering? 2 What harm if any is there in taking liquid petrolatum orally? 3 What analgesic is safe to use in a patient with myocarditis whose heart is being sustained with daily doses of digitalis? I fear the barbiturates, though practically all the pharmaceutical houses have a special formula which they declare has a wide margin of safety Please omit name. M D California

ANSWER—1 Psyllium may irritate by mechanical action, especially by forming masses, when it is not taken with a sufficient amount of water. It is best to take it well stirred in a glassful of water, and to drink a tumblerful of water afterward to prevent the possibility of lump formation. The mucilage remains largely undigested and appears in the stools, and is responsible for part of the laxative action

2 None unless it is taken in excessive dosage, when it is liable to "leak" out of the anus

3 Codeine (0.03 Gm.) is safe in such a patient and efficient, especially when combined with amidopyrine (0.30 Gm)

ACCIDENTAL SWALLOWING OF DOBELL'S SOLUTION AND OF HYDROGEN PEROXIDE

To the Editor—What is the treatment—if any is needed—of the accidental swallowing of (1) three fourths of a glass of Dobell's solution (about 5 to 6 ounces) (2) from one half to a glassful of 3 per cent hydrogen peroxide? (3) Please give immediate treatment—if any should be indicated—and treatment from twelve to twenty four hours after ingestion Please do not publish my name M D Missouri

ANSWER—1 If the patient took as much as 200 cc of Dobell's solution he would have ingested 3 Gm each of sodium borate and sodium bicarbonate and 0.6 Gm of phenol. As none of these exceed a possibly therapeutic dose, no treatment would be needed.

2 Such a dose is liable to produce considerable irritation of the gastric mucosa, its degree depending on the emptiness or fullness of the stomach

3 As the solution is rather acid, its irritant action may be lessened by the immediate administration of sodium bicarbonate. If emesis has not occurred vomiting might be induced or the stomach tube employed. The treatment of the subsequent gastritis would demand the use of a bland, smooth diet, such as milk and cereal gruels

RELIEF OF TRAUMATIC EPILEPSY AFTER WITHDRAWAL OF SPINAL FLUID

To the Editor—I recently heard a statement to the effect that the mere withdrawal of about 75 cc of spinal fluid and the replacement of the fluid with air to make an encephalogram would be likely to cause a permanent cessation of generalized periodic convulsions (traumatic epilepsy) in an adult whose attacks started six years after a supposed skull fracture. Is there any scientific support for such a statement? Is this view generally accepted? Is this procedure a diagnostic or therapeutic one? Please omit name city and state M D

ANSWER—It will be recalled that, when it became common practice to make encephalograms in cases of old head injury, it was found that some of the patients experienced relief from their previously almost constant headache after this procedure. Similarly, there have been cases of narcolepsy and of traumatic epilepsy with the similar result of more or less relief after the taking of an encephalogram. The method can only be considered a diagnostic one in cases of epilepsy, but in suggesting the procedure to patients and their relatives it is permissible to say that there may perhaps be some direct benefit as well

EFFECTS OF EPHEDRINE ON BLOOD SUGAR

To the Editor—Some months ago in an editorial you said that epinephrine throws sugar. Will the use of ephedrine do the same? Please omit name M D Illinois

ANSWER—Ephedrine has a tendency to increase the percentage of blood sugar acting similarly to epinephrine by increasing glycogenolysis in the liver

Book Notices

Clinical Physiology of the Eye By Francis Heed Adler M A M D F A C S Instructor in Physiology and Ophthalmology Medical School University of Pennsylvania Cloth Price \$6.00 Pp 406 with 82 illustrations New York Macmillan Company 1933

The need of a book, especially in English on the physiology of the eye has been apparent for many years as none of the textbooks on ophthalmology, with the exception of the recent volume by Duke-Elder, have paid attention to this subject. The author is a physiologist as well as a practitioner of ophthalmology. In the introduction it is stated that there has been no attempt to make an exhaustive treatise, but that by giving, in as simple terms as possible, the fundamental facts and generally accepted theories of how the eye functions an outline for study and a guide to the literature are furnished. It is natural that the author gives more attention to those subjects concerning which he has made personal contributions but it may be said that items of greatest importance are stressed and these subjects are treated in a way that even one without technical scientific training may read with much pleasure. The functions of the eye are considered in a more or less logical sequence, beginning with the protective mechanism externally and concluding with the optic nerve posteriorly, discussions on the external ocular muscles, the aqueous and the intra-ocular tension are reserved for the final chapters. A critical survey reveals certain statements worthy of mention. Fischer's experiments on the permeability of the cornea are cited as gospel, although they have not been corroborated. Heterochromia iridis is said to be due to a lesion of the cervical sympathetic ganglion. The superior colliculi are designated as the way station for the pupillomotor fibers en route to the third nerve nuclei. The action of drugs on the iris musculature is treated briefly. No mention is made concerning choriocarcinoma of the optic nerve. The work of Baumann with the ultramicroscope is not discussed in the chapters on the lens or vitreous. Those peculiar entoptic phenomena, which patients often inquire about, are made readily explainable. The influence of orthoptic exercises on the extra-ocular muscles and the retinal function is treated lightly, and Worth's conception of the fusion center does not explain entirely the reason for amblyopia and squint. The work of Polak on the visual paths of the cerebral cortex is not mentioned. The drawings, charts and pictures, some original, are well produced and descriptive. An excellent departure from the ordinary bibliography appended to each chapter is the inclusion not only of the concrete references used

in the text but also an extensive compilation of the pertinent literature. The type is large and a generous index concludes the volume. The author has accomplished his aim in a clear and concise manner, bringing to the student, the biochemist, the psychologist, the general physician, the physiologist, the neurologist and the ophthalmologist the first textbook limited to this subject and its extensive literature. It will readily find its place for those having any interest in the clinical physiology of the eye.

Hookworm Infestation By Clayton Lane M D Lieut Colonel Indian Medical Service (Retd.) Cloth Price \$6.25 Pp 310 with 36 illustrations New York & London Oxford University Press 1932

Hookworm disease has been widely used of late as a vehicle for carrying forward the propaganda for public health measures and for illustrating the significance of preventive medicine. Dr Charles Wardell Stiles, recently retired from the United States Bureau of Public Health, fittingly writes the foreword to this scholarly and incisive treatise. He closes this introduction, in which he emphasizes the slowness of progress in the mastery of this infection, with the terse sentence "Civilization was not made in a day." His plea is for health workers "to utilize to its full potentiality the church organizations and the school machinery of the world in the work of educating the masses to a higher conception of health and to the suppression of disease."

Colonel Lane's treatise is thoroughly interesting for many reasons. He incorporates in it the latest information in many-sided aspects of this thoroughly investigated field, he has well thought out opinions of his own on a number of significant features; and he expresses forcibly his criticisms of others and reinforces his own views with both facts and polemic arguments that excite admiration, if not always acquiescence.

The book is a splendid example of well considered public health work. It is well balanced in selection of material for inclusion, the author is critical alike of the significance of all conclusions presented by others, and of his own methods and results and, in all aspects of this many faceted subject, he keeps clearly in the foreground not only accurate and comprehensive scientific knowledge of hookworms and their relations to their hosts but also the control and ultimate elimination of hookworm disease.

The book opens with a succinct account of both sexes of the adult hookworms of man, *Necator americanus*, *Ancylostoma duodenale* and *A. braziliense* supplemented by a brief discussion of their valid names, host, habitats, geographic distribution and biology. Much attention is given to the extracorporeal life of the eggs and larval stages of these parasites. Eggs if not hatched live only three months. The conclusion is reached that infective larvae will live long enough to carry on infection from year to year. He criticizes Augustine's conclusion that the infective larvae die in the soil in Puerto Rico in from six to eight weeks. His results are interpreted as due to local dilution by migration rather than by death. Hookworm campaigns based on the acceptance of Augustine's conclusions are therefore liable to failure. Lane's own trapping experiments are cited in proof of the extent and significance of the migrating instinct or tropisms of the infective larvae.

These larvae live an aquatic life in the moisture around particles of earth. They can grow to the infective stage in the soil with as low a moisture content as 84 per cent. Development is suspended at 55 F, and death probably ensues at 21 F. Growth to infectivity is suspended at 104 F. Oxygen is necessary for development. Anaerobic conditions in the septic tank hasten their death. Larvae prior to the infective stage feed on aerobic bacteria such as *Bacillus coli*. Hydrogen ion concentration is most favorable at 7, and the limit of development is marked more sharply on the acid side than on the alkaline. Decomposition by anaerobiosis or hyperacidity destroys larvae. Light is deleterious to larvae, and gentle heat activates the infective stage.

Infestation through the skin is prevalent in the tropics and is the more primitive, but Lane is convinced from experiments that the oral route can also be utilized. However, in such cases the infective larval stage leaves the alimentary canal and follows the same route through the blood stream (rather than lymph) to the right heart, lungs, trachea, esophagus and stomach, to the small intestine, as does the worm entering by the cutaneous route.

The chapter on the pathologic damage induced by larval and adult worms is quoted and is the least satisfactory one in the book.

Much emphasis is laid on the value of an accurate method not merely of diagnosing the presence of hookworm in the patient, but of determining the weight of the infestation and of being able to detect light infestation. Obviously these are aspects essential not so much for diagnosis and treatment as for accurate knowledge of pathologic consequences, efficacy of therapeutic measures and exact evidence of the results of hookworm campaigns. To these ends Lane has rejected all methods of his predecessors and has devised the D C F, or direct centrifugal flotation method for mass control work, and the D C F F, the previous method pushed to finality, for critical control in the detection of ova in stools. An exhaustive and critical account of all methods is given in extenso only to conclude that "it is not possible from egg counts however exactly made, to deduce with any approach to accuracy the number of worms which a person harbours. To attempt it by inaccurate counting methods is surely futile."

The clinical symptoms and other ill effects of hookworm infestation are rather fully presented, and the varying opinions regarding the medical importance of the minor and fluctuating symptoms with which this chronic infestation is associated are reviewed.

Lane is very critical of those who believe that light, or even the lightest, infestations are negligible, and who would set a mathematical limit in numbers of worms, say 100 or even 25, which a child can harbor with impunity. The D C F F procedure gives "promise of determining, by the single factor control of disinfestation of simple hookworm infections, the extent to which the lightest infections are accompanied by detriment to the individual host. There is no justification for the confident assumption that they are personally immaterial."

Lane states that tissue immunity is marked in man except in the jejunum and ileum. Age immunity to the dog hookworm can be demonstrated in dogs but is as yet undemonstrated in man. He also holds that the reputed racial immunity of the Negro is unproved by the methods used.

The treatment for hookworm is discussed critically both as to the various anthelmintics used and as to the methods of determining their effects on the infection by Necator and Ancylostoma. "No obvious success has attended efforts to obtain, by combining drugs, a heightened parasitocidal effect with lessened toxicity to man, occasionally the reverse seems evident. Tetrachloroethylene has its fatal dose still undiscovered and shows no advance in efficiency over carbon tetrachloride. The latter is habitually given in quantity twice as great as the fatal dose. In such high doses it displays a potency not obviously greater than that of oil of chenopodium, while in amounts less than the minimum lethal dose it seems to have no claim to a place among efficient anthelmintics. Its record of cure and death lends no justification at all to any suggestion that it should be the great exception to the humane rule of medicine, namely, that the medicinal dose must be markedly lower than the fatal dose. Oil of chenopodium depends on ascaridole for its toxicity to both man and hookworm, the doses fatal to man and hookworm seem to overlap. The drug should be withheld unless the ascaridole content of the sample used is known and when given it must be dispensed with unflinching accuracy seeing how small an error may carry the dose over the narrow borderline between safety and possible catastrophe. The efficiency of thymol is clearly wrapped up in participation. On all the exact evidence which has been obtained and marshaled, *particulated* thymol is the drug of election for the individual, or for the mass treatment of hookworm infection. Some of the energy hitherto dissipated in the search for and testing of new anthelmintics, should be diverted to make plain the conditions in which this medicament best serves its valuable purpose. Its clean record in mild cases of infection sufficiently counters the criticism that to attempt to produce complete disinfestation in hookworm infection is immoral."

The final chapter on prevention discusses the various methods for preventing or reducing soil infestation by sanitary measures fitted for rural districts and the more primitive peoples. The final chapter on hookworm campaigns boldly takes the ground that such campaigns are in the interest of health. "Taking the world as a whole, with the possible exception of the

malarial organisms ankylostoma is responsible for more unhappiness and inefficiency than any other parasite and for the most part indirectly for no inconsiderable number of deaths. Practically all tropical countries are permeated with the worm, and in places where the conditions for its propagation are not unfavorable it may reduce four-fifths of the population to a continual state of chronic ill-health which is only terminated by their premature decease, commonly from some secondary infection." Lane therefore defends the campaign for complete disinfestation as the only really effective one and cheapest in the long run, now made possible by his D C F or, if presumably necessary, the D C F F, to get the last worm! "Take, for example, India. If freedom from infection increases the earning power of labor by a third only (25 per cent to 50 per cent being ordinary findings) the aggregate wages earned will be increased by £100,000,000 a year."

"India is but a sample, what applies to her applies to more than half the population of the world. And if disinfestation could be brought about by the wave of a wand how different would the tropical world be, different in sanitation, in health, in vigor, in riches, and in contentment. Towards this end is it not worth while to work, and spend, and wait?"

The National Encyclopedia. Editor in Chief Henry Suzzallo Ph.D. Sc.D. LL.D. President of the Carnegie Foundation for the Advancement of Teaching. Editorial Director W. W. Beardsley. In 10 volumes. Farkhold \$68. Leather \$89. De Luxe edition Morocco \$189. Various paginations with illustrations. New York P. F. Collier & Son Company 1932.

This new encyclopedia is planned especially for readers who wish accurate information and easily readable and up-to-date rather than exhaustive monographs on various topics. It has been prepared by a distinguished group of cooperating editors under the general direction of Prof. Henry Suzzallo, president of the Carnegie Foundation for the Advancement of Teaching. The book discusses thoroughly recent developments in history, politics, international affairs, war debts, the national election of 1932 and similar recent problems.

In the medical section of this encyclopedia organized and edited by Dr. Morris Fishbein, some 200 writers contributed. The total amount of space devoted to medicine is approximately 500,000 words. Thus the medical side of the encyclopedia may be considered modern, accurate, and altogether a fairly good guide to family medicine. Of particular value are the sections on anatomy and physiology.

The encyclopedia is published in ten volumes in a variety of bindings. It includes up-to-date maps of various sections of the world and is a most reliable and interesting reference work. Some of the longer articles are so well written and beautifully illustrated as to constitute in themselves good collateral reading in any field.

Les Ictères. Par Étienne Chabrol, professeur agrégé à la Faculté de médecine de Paris. Paper. Price 75 francs. Pp. 523 with 72 illustrations. Paris. Masson & Co. 1932.

This monograph represents the accumulation of more than twenty years' study of jaundice. The papers of the author and his colleagues make a list amounting to 129. Many references—German, American and English as well as French—are made throughout the text. One has the impression of a thorough scholarly but personal rather than impartial presentation of the subject. The work is divided into four main parts. The first is devoted to the laboratory study of icterus, with a description of the technique for clinical study of pigments, bile salts and cholesterol. A method of using the diazo reaction of Ehrlich as a ring test is described and preferred by comparison to the colorimetric van den Bergh test. The use of the stalagmometer is demonstrated with experimental and statistical clinical examples of results. Dissociated jaundice is explained and illustrated. A bibliography of principal French publications relative to the study of bile salts is included. In regard to stool analysis for urobilin the author remarks that the Einhorn method of duodenal intubation has permitted the abandonment of quantitative stool analyses, which have become of only historical interest. The second main division of the work is concerned with the physiopathology of the various forms of icterus. These are divided into icterus by retention and icterus by hyperhemolysis. The problem of the origin of bile pigments is briefly reviewed, the work of American investigators is considered as well as that of the English and German. He con-

cludes in favor of the hepatogenic origin of bile pigment although including the accessory function of the general reticulo-endothelial system. The third main division is an extended clinical description and classification of syndromes characterized by jaundice. The fourth section, on treatment, is brief and includes surgical indications as well as medical procedures. In general the work is representative of the French school, it covers the subject in an interesting and scholarly way, it is by one who has studied the problems of bile and blood pigments in the clinic and in the laboratory, and it is well worth the attention of American students of jaundice.

Obstetrícia operatória. Pelo Professor Raul Briquet, lente catedrático de clínica obstétrica da Faculdade de medicina de São Paulo. 1 e 2 milheiros. Fabrikoid. Pp 540 with 379 illustrations. São Paulo. Companhia Editora Nacional 1932.

Briquet acknowledges his indebtedness to the works of Brindeau, Bumm, Couvelaire, DeLee, Stockel and Winter for many of the illustrations. The index of authors is comprehensive and gives easy access to the bibliography, which is given in detail at the conclusion of each chapter. The alphabetical index makes it easy for the reader to locate pertinent subject matter and enhances the value of the work for reference purposes. The table of contents gives a brief outline of the material contained in the twenty-five chapters. In one of the early chapters the author summarizes the indications for obstetric operations and later presents a synopsis of the different types, which is followed by more detailed considerations of the various operative procedures. He is elaborate in his description of spinal anesthesia but gives little consideration to local and inhalation anesthesia. Chloroform and ether are briefly discussed, but ethylene and nitrous oxide are not presented as valuable anesthetic agents. A chapter is devoted to a consideration of fetal trauma, and there is a complete and excellent discussion of birth trauma. This is more or less of an innovation and would seem to be a valuable addition to a work on operative obstetrics, at least it stresses the importance of these injuries and places the responsibility on the obstetrician. The various infections and their surgical management are given the necessary consideration, and many of the postoperative complications are discussed extensively. A short chapter dealing with metabolic complications is appended, in which acidosis and alkalosis are given special consideration.

Local Provision for Higher Education in Saskatchewan. An Advisory Memorandum on University Policy Proposed at the Request of the University of Saskatchewan. By W. S. Learned and E. W. Wallace. Chancellor, Victoria University, Toronto. With a foreword by Henry Suzzallo, President of the Foundation. Bulletin No. 27. Paper. Pp. 30. New York: Carnegie Foundation for the Advancement of Teaching, 1932.

In his foreword, President Suzzallo points out that this report, apparently dealing with a local problem, has in reality a much broader significance. Both the situation analyzed and the tendencies recorded have been gathering weight and momentum in the United States and in Canada for many years. W. S. Learned of the foundation and Chancellor E. W. Wallace of Victoria University, Toronto, authors of the report, maintain that a junior college, so called, is not an incomplete fragment of a college locally administered for the sake of convenience. Not junior to anything and not a college "at all." They hold that it is the dimly recognized culmination or capstone of a system of secondary education and, as such, should be incorporated into the educational life of the community.

Aortitis aifilítica. Por Pedro Cossio, encargado de la sección cardiología de la cátedra de semiología del Profesor Padilla. Paper. Pp. 150 with 35 illustrations. Buenos Aires: El Ateneo, [n. d.]

Postmortem examination of bodies at the Institute of the Faculty of Medicine in Buenos Aires shows that 20 per cent of cardiovascular lesions are of syphilitic origin. In other countries the proportion is lower as the following figures seem to indicate: United States, 10 per cent; Germany, 6 per cent; and England, 5 per cent. The greater incidence in Buenos Aires is ascribed to a failure in the early diagnosis coupled with inadequate and incorrect therapy. With these facts in mind, the author has admirably set forth the pathologic anatomy, diagnostic criteria and roentgenologic aspects of syphilitic aortitis. This monograph is concise, clear and to the point, numerous illustrations enhance the value of the book.

Der Weg zur rationalen Therapie. Herausgegeben von Prof. Dr. A. Fraenkel. Vorträge gehalten zu Heidelberg vom 1. 3. August 1932 in der gemeinnützigen öffentlichen Krankenanstalt Speyerershof. Boards. Price 10.80 marks. Pp. 183 with 35 illustrations. Leipzig: Georg Thieme, 1933.

The "path to rational therapy," in the opinion of the editor of this book, lies through the quantitative application of specifically acting bodies in accordance with pharmacologic principles. This symposium, held at Speyerershof, an institution devoted to the treatment of chronic internal diseases is an attempt at exact study of dosage and the recording of the effects of medicines on man. In his introduction, Fraenkel stresses the point that internists should have as sharp indications and definite technique for their interventions as surgeons have for operations. In the present development of knowledge, a small, well studied group of medicines is much more desirable than a large number poorly understood. It is better for the physician to give nothing, when he is uncertain as to what to give, than to give a little medicine that is inactive or to give too much. Paul Martini gives a brief exposition of the mathematical basis of the clinical evaluation of medicines, elaborated more in detail in his *Methodenlehre*. Siebeck's discussion of the mercurial diuretics makes it evident that mersalyl (salyrgan) is the one that has almost displaced the others. Straub gives what one might call the "mechanics" and Fraenkel "quantitative considerations of digitalis therapy." For the latter purpose, intravenous administration must be preferred and strophanthin is most suitable, the minimal efficient dose of which the author places at from 0.3 to 0.4 mg. for the muscularly damaged heart. Insulin, thyroxine, arsphenamine, vitamin D, and liver therapy are dealt with in a practical quantitative manner, each by an expert in the respective field. The fact that much of this information is not yet available, excepting widely scattered in current literature, renders the report of this symposium highly desirable for the clinician who wishes to keep abreast of the latest developments and to be exact in his therapy.

Sex and Internal Secretions. A Survey of Recent Research. Edited by Edgar Allen, University of Missouri. With a foreword by Robert M. Yerkes, Yale University. Cloth. Price \$10. Pp. 951 with illustrations. Baltimore: Williams & Wilkins Company, 1932.

The Committee for Research in Problems of Sex, of the National Research Council, has guided a program of research on fundamental problems of sex for the last ten years. This book presents the results of a cooperative survey, organized by Dr. Edgar Allen. It represents the phases of research on internal secretions in relation to sex in which the committee has been most interested. The book is intended for those who are concerned in the progress of research in the problems of the biology and physiology of sex and the sex glands. The treatment of the subject is strictly scientific, but it is presented in a manner comprehensible to those with only a modest biologic background. The authors of the various sections are masters in their particular field of investigation. No finality is claimed for many of the subjects presented, as the aim of the book is to present only a summary of the most important advances of the work in this field of investigation. The first part of the book attempts to develop the subject in a fundamental manner. The first chapter, by Frank R. Lillie, is an appropriate introduction, a general biologic discussion of the subject. In the next chapter, Charles Danforth develops the interrelation of genetic and endocrine factors in sex. The succeeding chapters seek to develop the subject from the genetic background and an embryologic foundation. The general discussions are concluded by chapters on the deviation of sex and their causes, and metabolism and sex. The quantitative biologic estimation of sex is an important contribution of this part of the book. The following chapters deal with the specific sex hormone products: their biology, physiology and biochemistry. No previous book has presented such a vast fund of information on this subject in such a coherent and scholarly manner. The various chapters are presented in a scientific and interesting manner. The data are concisely summarized and a carefully chosen bibliography appears after each chapter. Publications of this type are distinctly valuable for contemporary research workers and they also serve a most useful purpose in stimulating correlated clinical research in this field of investigation. The book is indispensable for those interested in the scientific aspects of sex and internal secretions. It is also a valuable

addition to the library of any one who is interested in some of the more fundamental and recent advances in this subject. Physicians interested in any phase of endocrinology should read it

The Significance of Phosphoric Esters in Metabolism By Robert Robison, Ph.D. D.Sc. F.R.S. Professor of Biochemistry University of London. Cloth. Price \$2. Pp 104 with illustrations New York New York University Press 1932

This consists of three lectures related to pathologic chemistry, on the significance of phosphoric esters in metabolism, given under the auspices of the Herter Lecture Foundation in 1931, in the New York University and Bellevue Hospital Medical College. The Occurrence of Phosphoric Esters in Nature, Calcification of Cartilage and Bone, and Calcification in Vitro. The lectures include a survey of past research on the subjects closely related to the problems of most interest to the author, observations and findings of his own experimental studies accompanied by descriptive plates and postulated explanations to throw light on the mechanism of the chemistry of calcification and ossification. Tables of references are appended. The lectures are essentially of research interest.

The Tides of Life The Endocrine Glands in Bodily Adjustment By R. G. Hoskins, Ph.D. M.D. Director of Research Memorial Foundation for Neuro Endocrine Research Harvard Medical School. Cloth. Price \$3.50. Pp 352 with illustrations New York W. W. Norton & Company Inc. 1933

This is one of the best books so far written, for laymen, on the field of the endocrine glands. The author has a long experience as investigator in this field, particularly on the suprarenals. He has had long experience as editor of more scientific books on the endocrines and as editor of *Endocrinology*. He has the gift of simplicity and lucidity of expression combined with accuracy. Any one attempting in brief form to present an account of the significant aspects of the endocrines is in danger, on the one hand, of descending to marvel mongering, or of failing to do justice to the really remarkable advancement in human knowledge that has been made in the last four decades. Dr. Hoskins has escaped both of these pitfalls to a pleasing degree. While the book is primarily written for laymen and is both timely and welcome because of the great interest, the great confusion and the fog of fakery in the more popular literature on the subject, it may be read with much profit by physicians.

Child Psychology By Buford J. Johnson, Professor of Psychology in the Johns Hopkins University. Cloth. Price \$4. Pp 439 with 50 illustrations Springfield Ill. Charles C. Thomas 1932

This work is based on the experimental methods of observation and analysis. The author feels that the transition from simple mammalian behavior to complex adult psychology must bridge the period of childhood. It becomes obvious that a study of childhood is fundamental to the understanding of adult manifestations because the factors in the former are simpler, more direct and more apparent than in the latter. In workmanlike manner he proceeds to place the psychology of this period of life on a definite basis by making detailed observations of specific characteristics and analyzing the data. The results are recorded in chapters covering periods of growth, learning, infant responses, locomotion, manipulation, speech, attention and perception, thought, emotion, social behavior and personality and individual differences. To the everlasting frustration of the science affecting good women, from the harmless hausfrau to the executive mistress of a household establishment constituting the membership of the recent luxuriant growth of child study groups here is a book on 'child psychology'. The analytic school of matinee professors have pried pipped them into problems, complexes, egos and libidos. How the ladies will writhe when they learn the banal but disillusioning fact that all normal babies hold up their heads by the tenth day. No aspiring child study group will undertake to use this volume as a textbook. There is a forbidding frigidity of figures, a sturdiness of statistics that will immediately congeal the hot panting hunt for child psychology so called and its more sinister byways. Its cold catalogue of facts, its robust research review, its critical composure will freeze the rampant ardor of the skirt lifting head tossing, indignant laywomen, betrayed and deceived into prying between its covers. Dr.

Johnson will be suspected of a tongue-in-cheek maneuver by naively restoring a legitimate, long abused title to an innocently conceived scientific dissertation. From author to published work by way of eleven sculptured chapters, fifty tables and diagrams, 206 bibliographic references, and detailed author and subject indexes, there is no nonsense about this book. The genuineness of the contribution is reflected in the sterling character of its format.

Der dialektische Materialismus und die klinische Medizin Von Prof. J. Lifschitz. Allukrainische Gesellschaft zur Förderung der kulturellen Verbindungen mit dem Auslande. Paper. Pp 80. Kharkov Medwydaw 1932

This diatribe touches on various subjects ranging from metaphysics and psychology to an attack on the ideals of medical ethics and practice. Lifschitz sees in sovietism a panacea for all the supposed ills that may occur in the science and practice of medicine. In his bolshevistic propaganda he ridicules the methods of clinical medicine and is of the opinion that the main efforts of medicine should be directed toward public hygiene, sanitation and prophylaxis in general. He extols the socialization of medicine. He is an ardent advocate of the Marx-Lenin system, which he would introduce as the predominant concept in medical thought and practice. The pamphlet is difficult to read, and the thought is hard to follow. In this polemic the attitude is that of an iconoclast who offers nothing constructive, and who by invective, ridicule and destructive criticism would attempt to substitute a chimerical and unpractical system for one that has stood the test of time and still presents untold possibilities for the future of human welfare.

Éléments de pharmacodynamie spéciale Étude de l'action des divers médicaments Par Edgard Zunt, professeur à l'Université de Bruxelles. Tomes I et II. Paper. Price 190 francs per set. Pp 1271 with 167 illustrations. Paris. Masson & Cie 1932

This book is devoted chiefly to an exposition of the mode of action of various drugs. The therapeutic uses are touched on briefly and printed in small type. Nevertheless, purely from a didactic point of view and without attempting to hide its artificial character, the author employs a therapeutic classification for, after all, he hopes that an exact understanding of the principles and facts of pharmacodynamics may guide the practitioner in the administration of medicines and render pharmacotherapy more and more rational. It is certainly a classification that brings out in strong emphasis the most interesting utilizable effect of the drugs. Thus, quinidine is classified as an 'antifibrillant', salicylates and cinchophens are discussed under the heading 'anti-inflammatoires'. The book will undoubtedly become an indispensable part of any working library on the action and uses of drugs that aims to be comprehensive.

Fundamentals of Dietetics A Text Book for Nurses and Dietitians By Bertha M. Wood and Annie L. Weeks. Third edition. Cloth. Price \$1.75. Pp 254 with 20 illustrations. Philadelphia & London W. B. Saunders Company 1932

This volume will ably serve three purposes: as an introduction to dietetics as a recipe book for small-quantity cookery, and as a teaching guide for hospital dietitians. As a textbook of dietetics it lacks explanatory detail and is guilty of omissions (e.g. ketogenic and reducing diets) but is sufficiently comprehensive for the pupil for whom it is intended. The eighty recipes make the book serviceable to the nurse for reference when on private duty, while the logical arrangement of subject matter and simplicity of language make it a practical teaching aid in the classroom and laboratory.

Clínica quirúrgica. Por Pablo L. Mirizzi, profesor titular de clínica quirúrgica de la Facultad de medicina de Córdoba. Tomos II e III. Paper. Pp 308 304 with illustrations. Córdoba. Librería El Ateneo 1931 1932

These two volumes discuss varied surgical lesions. Conditions emphasized are acute and chronic diseases of the gall-bladder, chronic mastitis, malignant conditions of the breast and osteomyelitis. To each subject one chapter is allotted, with a complete case history followed by a discussion including surgical technique. A bibliography is appended to each chapter. The subjects are handled interestingly, but nothing new has been added to scientific literature.

cludes in favor of the hepatogenic origin of bile pigment although including the accessory function of the general reticulo-endothelial system. The third main division is an extended clinical description and classification of syndromes characterized by jaundice. The fourth section, on treatment, is brief and includes surgical indications as well as medical procedures. In general the work is representative of the French school; it covers the subject in an interesting and scholarly way, it is by one who has studied the problems of bile and blood pigments in the clinic and in the laboratory, and it is well worth the attention of American students of jaundice.

Obstetrícia operatória. Pelo Professor Raul Briquet lente catedrático de clínica obstétrica da Faculdade de medicina de São Paulo. 1 e 2 milheiros. Fabrício. Pp 540 with 379 illustrations. São Paulo. Com panha Editora Nacional 1932

Briquet acknowledges his indebtedness to the works of Brindeau, Bumm, Couvelaire, DeLee, Stöckel and Winter for many of the illustrations. The index of authors is comprehensive and gives easy access to the bibliography, which is given in detail at the conclusion of each chapter. The alphabetical index makes it easy for the reader to locate pertinent subject matter and enhances the value of the work for reference purposes. The table of contents gives a brief outline of the material contained in the twenty-five chapters. In one of the early chapters the author summarizes the indications for obstetric operations and later presents a synopsis of the different types, which is followed by more detailed considerations of the various operative procedures. He is elaborate in his description of spinal anesthesia but gives little consideration to local and inhalation anesthesia. Chloroform and ether are briefly discussed, but ethylene and nitrous oxide are not presented as valuable anesthetic agents. A chapter is devoted to a consideration of fetal trauma, and there is a complete and excellent discussion of birth trauma. This is more or less of an innovation and would seem to be a valuable addition to a work on operative obstetrics, at least it stresses the importance of these injuries and places the responsibility on the obstetrician. The various infections and their surgical management are given the necessary consideration, and many of the postoperative complications are discussed extensively. A short chapter dealing with metabolic complications is appended, in which acidosis and alkalosis are given special consideration.

Local Provision for Higher Education in Saskatchewan. An Advisory Memorandum on University Policy Proposed at the Request of the University of Saskatchewan. By W. S. Learned and E. W. Wallace, Chancellor Victoria University, Toronto. With a foreword by Henry Suzzallo, President of the Foundation. Bulletin No. 27. Paper. Pp. 30. New York: Carnegie Foundation for the Advancement of Teaching, 1932.

In his foreword, President Suzzallo points out that this report, apparently dealing with a local problem, has in reality a much broader significance. Both the situation analyzed and the tendencies recorded have been gathering weight and momentum in the United States and in Canada for many years. W. S. Learned of the foundation and Chancellor E. W. Wallace of Victoria University, Toronto, authors of the report maintain that a junior college so called, is not an incomplete fragment of a college locally administered for the sake of convenience. Not "junior" to anything and not a college at all. They hold that it is the dimly recognized culmination or capstone of a system of secondary education and as such, should be incorporated into the educational life of the community.

Aeritile sífilítica. Por Pedro Cossio, encargado de la sección cardiología de la cátedra de semiología del Profesor Padilla. Paper. Pp. 150 with 35 illustrations. Buenos Aires: El Ateneo, 1932.

Postmortem examination of bodies at the institute of the Faculty of Medicine in Buenos Aires shows that 20 per cent of cardiovascular lesions are of syphilitic origin. In other countries the proportion is lower as the following figures seem to indicate: United States 10 per cent, Germany 6 per cent and England 5 per cent. The greater incidence in Buenos Aires is ascribed to a failure in the early diagnosis coupled with inadequate and incorrect therapy. With these facts in mind, the author has admirably set forth the pathologic anatomy, diagnostic criteria and roentgenologic aspects of syphilitic aortitis. This monograph is concise, clear and to the point, numerous illustrations enhance the value of the book.

Der Weg zur rationalen Therapie. Herausgegeben von Prof. Dr. A. Fraenkel. Vorträge gehalten zu Heidelberg vom 1. 3. August 1932 in der gemeinsamen öffentlichen Krankenanstalt Speyererhof. Boards. Price 10.80 marks. Pp. 183 with 35 illustrations. Leipzig: Georg Thieme, 1933.

The "path to rational therapy," in the opinion of the editor of this book, lies through the quantitative application of specifically acting bodies in accordance with pharmacologic principles. This symposium, held at Speyererhof, an institution devoted to the treatment of chronic internal diseases, is an attempt at exact study of dosage and the recording of the effects of medicines on man. In his introduction, Fraenkel stresses the point that internists should have as sharp indications and definite technic for their interventions as surgeons have for operations. In the present development of knowledge a small, well studied group of medicines is much more desirable than a large number poorly understood. It is better for the physician to give nothing, when he is uncertain as to what to give, than to give a little medicine that is inactive or to give too much. Paul Martini gives a brief exposition of the mathematical basis of the clinical evaluation of medicines, elaborated more in detail in his *Methodenlehre*. Siebeck's discussion of the mercurial diuretics makes it evident that mersalyl (salyrgan) is the one that has almost displaced the others. Straub gives what one might call the "mechanics" and Fraenkel "quantitative considerations of digitalis therapy. For the latter purpose, intravenous administration must be preferred and strophanthin is most suitable, the minimal efficient dose of which the author places at from 0.3 to 0.4 mg. for the muscularly damaged heart. Insulin, thyroxine, arsphenamine, vitamin D, and liver therapy are dealt with in a practical quantitative manner, each by an expert in the respective field. The fact that much of this information is not yet available, excepting widely scattered in current literature, renders the report of this symposium highly desirable for the clinician who wishes to keep abreast of the latest developments and to be exact in his therapy.

Sex and Internal Secretions. A Survey of Recent Research. Edited by Edgar Allen, University of Missouri. With a foreword by Robert M. Yerkes, Yale University. Cloth. Price \$10. Pp. 501 with illustrations. Baltimore: Williams & Wilkins Company, 1932.

The Committee for Research in Problems of Sex, of the National Research Council has guided a program of research on fundamental problems of sex for the last ten years. This book presents the results of a cooperative survey organized by Dr. Edgar Allen. It represents the phases of research on internal secretions in relation to sex in which the committee has been most interested. The book is intended for those who are concerned in the progress of research in the problems of the biology and physiology of sex and the sex glands. The treatment of the subject is strictly scientific, but it is presented in a manner comprehensible to those with only a modest biologic background. The authors of the various sections are masters in their particular field of investigation. No finality is claimed for many of the subjects presented, as the aim of the book is to present only a summary of the most important advances of the work in this field of investigation. The first part of the book attempts to develop the subject in a fundamental manner. The first chapter by Frank R. Lillie, is an appropriate introduction, a general biologic discussion of the subject. In the next chapter, Charles Danforth develops the interrelation of genetic and endocrine factors in sex. The succeeding chapters seek to develop the subject from the genetic background and an embryologic foundation. The general discussions are concluded by chapters on the deviation of sex and their causes, and metabolism and sex. The quantitative biologic estimation of sex is an important contribution of this part of the book. The following chapters deal with the specific sex hormone products, their biology, physiology and biochemistry. No previous book has presented such a vast fund of information on this subject in such a coherent and scholarly manner. The various chapters are presented in a scientific and interesting manner. The data are concisely summarized and a carefully chosen bibliography appears after each chapter. Publications of this type are distinctly valuable for contemporary research workers and they also serve a most useful purpose in stimulating correlated clinical research in this field of investigation. The book is indispensable for those interested in the scientific aspects of sex and internal secretions. It is also a valuable

addition to the library of any one who is interested in some of the more fundamental and recent advances in this subject. Physicians interested in any phase of endocrinology should read it

The Significance of Phosphoric Esters in Metabolism By Robert Robison Ph.D. D.Sc. F.R.S. Professor of Biochemistry University of London Cloth Price \$2 Pp 104 with illustrations New York New York University Press 1932

This consists of three lectures related to pathologic chemistry, on the significance of phosphoric esters in metabolism given under the auspices of the Herter Lecture Foundation in 1931, in the New York University and Bellevue Hospital Medical College. The Occurrence of Phosphoric Esters in Nature, Calcification of Cartilage and Bone, and Calcification in Vitro. The lectures include a survey of past research on the subjects closely related to the problems of most interest to the author, observations and findings of his own experimental studies accompanied by descriptive plates, and postulated explanations to throw light on the mechanism of the chemistry of calcification and ossification. Tables of references are appended. The lectures are essentially of research interest.

The Tides of Life The Endocrine Glands in Bodily Adjustment. By R. G. Hoskins Ph.D. M.D. Director of Research Memorial Foundation for Neuro Endocrine Research Harvard Medical School Cloth. Price \$3.50 Pp 342 with illustrations New York W. W. Norton & Company Inc 1933

This is one of the best books so far written, for laymen, on the field of the endocrine glands. The author has a long experience as investigator in this field, particularly on the suprarenals. He has had long experience as editor of more scientific books on the endocrines and as editor of *Endocrinology*. He has the gift of simplicity and lucidity of expression combined with accuracy. Any one attempting in brief form to present an account of the significant aspects of the endocrines is "in danger, on the one hand, of descending to marvel mongering, or of failing to do justice to the really remarkable advancement in human knowledge that has been made in the last four decades." Dr Hoskins has escaped both of these pitfalls to a pleasing degree. While the book is primarily written for laymen and is both timely and welcome because of the great interest, the great confusion and the fog of fakery in the more popular literature on the subject, it may be read with much profit by physicians.

Child Psychology By Buford J. Johnson Professor of Psychology in the Johns Hopkins University Cloth Price \$4 Pp 439 with 50 illustrations Springfield Ill. Charles C. Thomas 1932

This work is based on the experimental methods of observation and analysis. The author feels that the transition from simple mammalian behavior to complex adult psychology must bridge the period of childhood. It becomes obvious that a study of childhood is fundamental to the understanding of adult manifestations because the factors in the former are simpler, more direct and more apparent than in the latter. In workmanlike manner he proceeds to place the psychology of this period of life on a definite basis by making detailed observations of specific characteristics and analyzing the data. The results are recorded in chapters covering periods of growth, learning, infant responses locomotion manipulation, speech attention and perception thought, emotion, social behavior and personality and individual differences. To the everlasting frustration of the science affecting good women from the harmless hausfrau to the executive mistress of a household establishment constituting the membership of the recent luxuriant growth of child study groups, here is a book on "child psychology." The analytic school of *matinée* professors have "piped" them into problems, complexes, egos and libidos. How the ladies will writhe when they learn the banal but disillusioning fact that all normal babies hold up their heads by the tenth day. No aspiring child study group will undertake to use this volume as a textbook. There is a forbidding frigidity of figures a sturdiness of statistics that will immediately congeal the hot panting hunt for child psychology, so called and its more sinister byways. Its cold catalogue of facts its robust research review its critical composure will freeze the rampant ardor of the skirt lifting head tossing, indignant laywomen, betrayed and deceived into prying between its covers. Dr

Johnson will be suspected of a tongue-in-cheek maneuver by naively restoring a legitimate, long abused title to an innocently conceived scientific dissertation. From author to published work by way of eleven sculptured chapters, fifty tables and diagrams, 206 bibliographic references, and detailed author and subject indexes, there is no nonsense about this book. The genuineness of the contribution is reflected in the sterling character of its format.

Der dialektische Materialismus und die klinische Medizin Von Prof. J. Lifschitz Allukrainische Gesellschaft zur Förderung der kulturellen Verbindungen mit dem Auslande Paper Pp 80 Kharkov Medwydaw 1932

This diatribe touches on various subjects ranging from metaphysics and psychology to an attack on the ideals of medical ethics and practice. Lifschitz sees in sovietism a panacea for all the supposed ills that may occur in the science and practice of medicine. In his bolshevistic propaganda he ridicules the methods of clinical medicine and is of the opinion that the main efforts of medicine should be directed toward public hygiene, sanitation and prophylaxis in general. He extols the socialization of medicine. He is an ardent advocate of the Marx-Lenin system, which he would introduce as the predominant concept in medical thought and practice. The pamphlet is difficult to read, and the thought is hard to follow. In this polemic the attitude is that of an iconoclast, who offers nothing constructive, and who by invective, ridicule and destructive criticism would attempt to substitute a chimerical and unpractical system for one that has stood the test of time and still presents untold possibilities for the future of human welfare.

Éléments de pharmacodynamie spéciale Étude de l'action des divers médicaments Par Edgard Zunt professeur à l'Université de Bruxelles Tomes I et II Paper Price 180 francs per set Pp 1271 with 167 illustrations Paris Masson & Cie 1932

This book is devoted chiefly to an exposition of the mode of action of various drugs. The therapeutic uses are touched on briefly and printed in small type. Nevertheless purely from a didactic point of view and without attempting to hide its artificial character, the author employs a therapeutic classification, for, after all, he hopes that an exact understanding of the principles and facts of pharmacodynamics may guide the practitioner in the administration of medicines and render pharmacotherapy more and more rational. It is certainly a classification that brings out in strong emphasis the most interesting utilizable effect of the drugs. Thus quinidine is classified as an "antifibrillant" salicylates and cinchophens are discussed under the heading "anti inflammatoires." The book will undoubtedly become an indispensable part of any working library on the action and uses of drugs that aims to be comprehensive.

Fundamentals of Dietetics A Text Book for Nurses and Dietitians By Bertha M. Wood and Annie L. Weeks Third edition Cloth. Price \$1.75 Pp 254 with 20 illustrations Philadelphia & London W. B. Saunders Company 1932

This volume will ably serve three purposes as an introduction to dietetics, as a recipe book for small-quantity cookery, and as a teaching guide for hospital dietitians. As a textbook of dietetics it lacks explanatory detail and is guilty of omissions (e.g. ketogenic and reducing diets) but is sufficiently comprehensive for the pupil for whom it is intended. The eighty recipes make the book serviceable to the nurse for reference when on private duty, while the logical arrangement of subject matter and simplicity of language make it a practical teaching aid in the classroom and laboratory.

Clínica quirúrgica Por Pablo L. Mirizzi profesor titular de clínica quirúrgica de la Facultad de medicina de Córdoba Tomos II e III Paper Pp 308 305 with illustrations Córdoba Librería El Ateneo 1931 1932

These two volumes discuss varied surgical lesions. Conditions emphasized are acute and chronic diseases of the gall-bladder, chronic mastitis, malignant conditions of the breast, and osteomyelitis. To each subject one chapter is allotted, with a complete case history followed by a discussion including surgical technique. A bibliography is appended to each chapter. The subjects are handled interestingly, but nothing new has been added to scientific literature.

Medicolegal

Use of Patient as Clinical Material

(*Inderbitzen v. Lane Hospital (Calif.) 12 P (2d) 744*)

The patient sued the defendant hospital corporation and its managers for alleged malpractice in connection with her confinement. When she entered the hospital she was examined, according to the evidence by a young man whom she believed to be a medical student and by an older man summoned when she demanded that a doctor be called. Both made rectal and vaginal examinations without sterilizing their hands. She was then taken to the delivery room and there examined intimately two or three times by each of ten to twelve young men whom the patient believed to be students. The evidence purported to show that in spite of her protests she was several times rolled over and palpated about the body and on protest told to 'shut up.' A physician testifying on her behalf at the trial stated that he examined her two months after her child was born and that there was then a tear in her uterus which was infected and discharging profusely. At the conclusion of the evidence the defendants moved that the suit be dismissed because the charges of negligence and carelessness had not been proved. The trial court granted the motion and its action was in the first instance affirmed by the district court of appeal first district division number 1, California (7 P (2d) 1049 THE JOURNAL, Oct. 22 1932 p. 1454). The district court of appeal, however, reconsidered the case and reversed its prior decision.

It is the general rule said the court that the propriety or impropriety of particular medical treatment can be established only by expert medical testimony. This rule is however, subject to the exception that if the particular matter is one of general knowledge expert evidence is not necessary. In the present case, no medical expert testified that it was negligence for men with unsterilized hands to make rectal and vaginal examinations of the patient. But it has been held to be proper for a court to take judicial notice of the necessity for the use of ordinary care in sterilizing a hypodermic needle or the flesh into which it is to be inserted in administering a local anesthetic (*Barham v. Hiding* 210 Calif. 206 291 P. 173), and courts will likewise take judicial notice of the danger of infection to a woman about to give birth to a child from a vaginal examination performed with unsterilized hands. The repeated examinations of the patient, continued the court while she was in labor by ten or twelve men causing her to scream and protest, and the levity and rudeness that it is claimed was displayed, present "anything but a pretty picture."

As was said by the New York Court of Appeals in *Stone v. Illman M. Eisen Co.* 219 N. Y. 205, 114 N. E. 44

Decent and respectful treatment is implied in the contract from the confidential relation of the parties and especially because of the necessary exposure of the person required of the patient in connection with the services to be performed pursuant to the contract.

On behalf of the defendant the court was urged to presume that the treatment to which the patient was subjected was necessary and proper, or at least to hold that the court could not hold such treatment to be improper in the absence of medical testimony to that effect. Common sense, however, said the court tells any reasonable person that such treatment at the hands of so many is unnecessary and improper. Scientific knowledge is not essential for the determination of an obvious fact. This treatment, at least after the patient had objected to it, constituted an assault on her or trespass to her person. A physician or a medical student has no more right to lay hands on a patient against her will than has a layman.

For the reasons stated the action of the trial court in dismissing the suit was reversed.

Evidence Testimony of Medical Experts Invading Province of Jury—The plaintiff slipped and fell immediately thereafter he felt a stinging sensation through the small of his back. About twenty minutes later he felt faint and suffered a series of hemorrhages. Eventually he became unable to "navigate his feet" which in the opinion of a medical expert was due to some incoordination, lack of muscular coordination and is due possibly to some condition in his spinal cord. Alleging that his disability was caused solely by

the fall the plaintiff brought suit on an insurance policy which provided for certain benefits for effects resulting directly and exclusively of all other causes from bodily injuries sustained wholly through external violent and accidental means. The insurer contended that the disability was the result of gastric ulcers present at the time of the fall. From a judgment for the plaintiff the insurer appealed to the Supreme Court of Iowa. The insurer complained that the trial court had permitted several medical experts to testify, in effect that the fall was the sole proximate cause of the plaintiff's present disability. This testimony, said the Supreme Court was a clear invasion of the province of the jury and was improper. In a case of this kind, it may be important for an expert to enlighten the jury on subjects of a technical or scientific character. An expert may be permitted to express an opinion as to whether in his judgment, a certain condition, arising in a scientific or technical field may have been brought about from certain causes. An expert, however may never be permitted to invade the province of the jury by expressing an opinion as to what in fact did cause that condition. The judgment was reversed and the cause remanded for a new trial—*Justis v. Union Mut. Casualty Co. (Iowa) 244 N. W. 696*

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

- Analysis of Factors Entering into Radium Pack Intensities. M. C. Reinhard. Buffalo.—p. 136
- Cancer Mortality of Amsterdam, Holland, by Religious Sects. F. L. Hoffman.—p. 142

Hydrogen Ion Concentration of Blood in Cancer.—Using the method of Hastings and Sendroy, as modified by McDonald and co workers, Ely studied the p_H of the blood of normal subjects at rest, normal subjects during activity, untreated cancer patients, previously treated cancer patients, patients with benign tumors, a group of cancer patients showing the effect of treatment on the blood p_H , a group of tumor patients designed to show any relation between the blood p_H and existing anemia, fracture cases and a miscellaneous group of patients presenting malignant growths. He observed that cases of uncomplicated and untreated skin and superficial cancers usually have a normal blood p_H . Uncomplicated cases of untreated and advanced internal cancers usually have a blood p_H above normal. Patients with benign tumors usually have a blood p_H above normal. In a number of pathologic conditions other than cancer the blood p_H is elevated, comparably to that in cancer. A blood p_H persistently high in spite of treatment appears to be a bad prognostic sign in cancer. The p_H of the blood by itself is of little, if any, diagnostic value in cancer.

Kraurosis Vulvae.—Goldberger presents an analysis of thirteen cases of kraurosis vulvae of which eight were treated by vulvectomy. He studied thirteen cases of carcinoma in order to determine a relationship to kraurosis. Both from the literature and from his analysis, carcinoma was found to develop in kraurosis in 50 per cent of the cases. Unsuspected carcinoma was present in two of the eight cases treated by vulvectomy. He observed that roentgen and hormonal therapy was ineffective. Vulvectomy is the treatment for the cure of kraurosis and the prevention of carcinoma.

Bercovitz Test for Pregnancy.—King points out that the value of the Bercovitz pupillary reaction in pregnancy, although it is exceedingly simple is greatly impaired by the difficulty in reading the result and by the fact that much depends on the personal equation of the observer. It consists in the instillation into one eye of a few drops of the patient's blood, pregnancy being indicated by either a dilatation, a contraction, or an alternation of the two, in contrast with the other eye in which there is no change. In 107 cases of proved pregnancy the author observed a positive result in 68 per cent, a doubtful response in 10 per cent and a negative result in 21 per cent. Epinephrine, 1:1,000, will give similar reactions to some extent. In seven cases out of forty-five, epinephrine gave a correct positive result when the blood test was either negative or doubtful. The reaction is not constant in the same woman at different examinations. The reaction disappears early in the puerperium in most but not in all cases. In 108 tests on nonpregnant persons there were four false positive responses and eleven doubtful reactions.

Endocarditis as Complication of Pregnancy.—From his study of two cases, Mengert states that subacute bacterial endocarditis does not seem to affect materially the course of pregnancy, labor and the puerperium. Pregnancy complicated by subacute bacterial endocarditis should be allowed to proceed to normal conclusion because the mother's course is almost certain to terminate fatally and it is extremely doubtful if sacrifice of the child contributes, even in the smallest way, to her chance of survival. Delivery by the most conservative means possible after full dilatation of the cervix with plentiful first stage analgesia is the obstetric treatment of choice. Cesarean section is justified only in the interest of the baby when the mother is dying. The babies seem to do well if they are not too premature at birth.

Epinephrine in Treatment of Puerperal Uterus.—Urner reports a case of acute inversion of the puerperal uterus in which the intramuscular injection of epinephrine seemed to have been effective in producing relaxation of the uterus and cervix and to have greatly facilitated manual replacement. There is little doubt of its value in protecting the patient from further shock during operation. The author suggests

that epinephrine is a valuable adjunct in the reposition of the acutely inverted puerperal uterus by either manual or operative method.

Humoral Agents and Gallbladder Contraction.—In their experiments on dogs, Voegtlin and his associates attempted to determine whether some product of the digestion of fat and egg yolk may excite the gallbladder to contract on being absorbed. This was done to ascertain whether some humoral agent other than cholecystokinin may be concerned in gallbladder evacuation on ingesting egg yolk and cream or olive oil. Their results indicate that no other humoral agent than cholecystokinin is concerned in gallbladder contraction and

evacuation. Egg yolk injected intravenously usually had no effect on liver volume, intragallbladder pressure and blood pressure. Emulsified olive oil injected intravenously in doses that increase the liver volume caused an artificial or mechanical rise of the intragallbladder pressure. From 3 to 5 cc. of a 0.2 per cent solution of hydrochloric acid and 10 cc. of a 5 per cent solution of sodium chloride, as well as fresh pancreatic juice (from 10 to 50 cc.), had no effect on the gallbladder when injected intravenously. Bile or bile salts injected intravenously tended to decrease the tone of the gallbladder. Olive oil and egg yolk digests were too toxic to use intravenously for their work. When such digests were extracted by the method for obtaining cholecystokinin from the duodenal mucosa, no gallbladder excitant was obtained. Oleic acid (from 1 to 5 cc.) and glycerin (from 3 to 5 cc.) given intravenously had no effect on the gallbladder or liver volume. Chyle, containing from 1 to 25 per cent fat and obtained from a dog after being fed egg yolks and cream on being injected intravenously in amounts of from 10 to 120 cc did not cause the gallbladder to contract and evacuate in anesthetized or unanesthetized dogs.

Effect of Epinephrine on Normal Iris.—Sawyer and Schlossberg state that epinephrine, if instilled for a sufficiently long time into the conjunctival sac of normal cats or of rabbits, exerts an effect on the muscles of the iris. The effect of minimal doses of instilled epinephrine in cats is to cause a constriction of the pupil. Larger amounts of the drug produce a distinct mydriasis in the instilled eye, which is in some cases preceded and followed by a period of contraction. Previous removal of the nictitating membrane in cats greatly increases the effect of epinephrine instilled into the otherwise normal eye. The authors took measurements of the pupils by means of a millimeter scale held close in front of the eyes and at right angles to the vertical pupillary opening. The eyes were subjected to a standard illumination. The epinephrine solutions for instillation were made up fresh for each experiment, 1:10,000 and 1:2,000 dilutions were employed. The solution was instilled in only one eye, the other was used as control. The instillation was made by holding apart the eyelids and dropping in a sufficient amount of solution to flood the eyeball. Every few minutes the instilled solution was removed by wiping the eye with cotton and fresh drops were added. The time during which the epinephrine solution was kept in contact with the conjunctiva varied from five to thirty minutes. Intravenous injection of epinephrine into a normal animal showing contraction of the pupil of one eye from a previous instillation of epinephrine produced a more striking and more persistent mydriasis in that eye than in the normal one. Intravenous injection of epinephrine into a normal animal showing dilatation of one pupil from a previous instillation produced in the instilled eye a more marked mydriasis than in the other eye. In this instance the mydriasis of the instilled eye remained for a much longer time after the normal pupil had reached its original diameter.

Larval Therapy in Pyogenic Infections—Weil and his associates used maggot therapy in twenty-nine cases of a variety of pathogenic organisms such as *Streptococcus hemolyticus*, *staphylococcus*, *pneumococcus*, *Bacillus tuberculosis*, *B. coli* and *B. welchii*. Included in this group of infections were felons, tuberculous inguinal adenitis, large areas of cellulitis, infected abdominal incisions following appendical abscess, infected amputation stumps, including also six cases of gas bacillus infection. The entire group of patients except one made splendid recoveries with good return of function. Considerable work must yet be done to place the therapy on a practical basis. The authors suggest the name 'larval therapy'. No detrimental effects or complications have developed from the use of larvae prepared by their present method of sterilization. The authors believe that the use of an iodine solution to sterilize the partly grown maggots that show contamination after egg sterilization just before they are implanted in the wound, is of great value. They have placed the time element of implantation on a practical working basis. They did not encounter opposition from their patients. Their results compare favorably to any other form of treatment and in most instances are far superior. Its value in the treatment of gas bacillus infection and other soft tissue infections is exceptional. They have never observed any deleterious activity of the larvae on normal viable human tissues. The larvae show an unusual activity against abnormal or malignant structures. The authors believe that aside from the scavenger action, the larvae produce a definite excretory proteolytic substance which hastens liquefaction of devitalized tissue.

Pneumothorax in Pulmonary Suppuration.—According to Bendove, the difference in the elasticity and consistency of the diseased and healthy lung tissue as well as the difference in the intrapulmonary and intrapleural pressures make it possible for the air introduced into the pleural cavity to localize over the diseased portion without curtailing much of the function of the nondiseased portion in the treated lung. This selective type of pneumothorax can be instituted only in recent cases of pulmonary suppuration when the lesion is soft and plastic. Every case of acute pulmonary suppuration should first be treated expectantly, but, if no spontaneous cure has occurred within four weeks after the diagnosis has definitely been made, active surgical intervention is indicated and pneumothorax of the selective type is the least radical and most effective therapy at that time. A successful selective pneumothorax immobilizes the diseased portion without reducing the vital capacity, stimulates drainage, entails little respiratory and circulatory changes and causes little discomfort to the patient both at the initiation of the treatment as well as at the subsequent reinspirations. The insufflatory amount should vary from 150 to 250 cc., and the intervals from three to five days. As the patient improves, the periods between insufflations are increased. The collapse should be maintained at least three months after the abatement of all subjective symptoms. In cases of chronic pulmonary suppuration with indurated rigid lesions and pleuretic adhesions, the selective action of artificial pneumothorax can never be elicited. Pneumothorax alone is of little therapeutic value in such cases, though it still finds its use as a preparatory procedure to radical thoracic surgery.

Internal Drainage and Atelectasis—The prophylaxis and treatment of postoperative pulmonary atelectasis demands a clear understanding of the mechanism of its etiologic factors, namely internal drainage. By internal drainage, Lubin means the movement of secretions from place to place within the tracheobronchial tree so that bronchi are occluded and infection spreads. The movements of these secretions are dependent on the posture of the patient, the nature and quantity of the tracheobronchial secretions and the size and course of the bronchial stems. Buccal and nasal secretions by gravitating into the tracheobronchial tree even during the presence of the cough reflex, play a significant part in the production of pulmonary atelectasis and pneumonia. The early recognition of postoperative pulmonary atelectasis is important for two reasons: (1) it allows an earlier institution of treatment and facilitates a more prompt return of the atelectatic lobe to normal, and (2) it obviates the dreaded postoperative pneumonia which may occur in atelectasis of longer duration. The administration of postural exercises, carbon dioxide inhalations and expectorants are of proved value in the treatment of postoperative pulmonary atelectasis. Bronchoscopy, in specific instances, deserves a place in the armamentarium for the prophylaxis and treatment. An appreciation of internal drainage and the proper application of its fundamental factors can diminish the incidence of postoperative pulmonary atelectasis and postoperative pneumonia.

Removal of Toe Nail—Lapidus offers a plastic operation for complete and permanent removal of the toe nail in cases of onychogryposis, subungual osteoma and any deformity of the toe nail in which complete removal is indicated. The operation consists of a U-shaped incision surrounding the toe nail the free ends of the U extending proximally to the head of the basal phalanx. Another slightly concave incision, opened distally, is made through the skin covering the root of the nail. This incision crosses the long axis of the toe and connects the two sides of the U. The dorsal structures, consisting of the edge of the skin around the nail, the matrix of the nail, and the nail itself, are entirely removed. About one half the distal portion of the terminal phalanx is exposed subperiosteally and resected. This leaves a short dorsal and long plantar flap. The plantar, tongue shaped flap is turned over the stump of the terminal phalanx and sutured to the shorter dorsal flap. In cases of primary union of the wound the patient may resume his work in from two to three weeks, wearing the usual shoes.

Tuberculosis of Thyroid—Tuberculous lesions of the thyroid have been reported in from 4 to 12 per cent of people

dying of active tuberculosis and in an average of 0.34 per cent of the thyroids removed at operation for all causes. The Van Ravenswaays state that, of the 107 cases reported in the literature, active tuberculosis was observed elsewhere in the body in fourteen cases. Among the factors that may be concerned in the development of this condition are preexisting goiter, the presence of lymphoid tissue within the thyroid, hyperthyroidism and a normally high tissue resistance to tuberculosis. Clinically, the types of lesion seen vary between two extremes: a necrotic type with caseation or liquefaction and a fibrotic type associated with giant cells and lymphoid cells. The preoperative diagnosis is possible only by aspiration of a cold abscess or with material obtained from a draining sinus. Not infrequently there are lesions in the thyroid that may be confused with tuberculosis. The authors report a typical case of tuberculosis of the thyroid in a man, aged 43.

Diverticulosis and Diverticulitis—Barrett believes that constipation, putrefactions, infections and irritations produce changes in the intestine that make it subject to diverticulosis. By keeping the intestinal tract fit, changes that favor the development of diverticulosis may be avoided. Diverticulosis furnishes pockets which become filled with fecal masses, stercoroliths, foreign substances and bacteria, which result in reactions known as *diverticulitis* and *peridiverticulitis*. Bacteria invade the intestinal wall at such distances as to make "paradiverticulitis" an appropriate term for the resulting reaction. The reactions in the intestinal wall result in spastic and organic obstruction or stenosis. The passing of bacteria through the thinned diverticula or the thickened infected or ruptured intestinal wall leads to peritoneal and mesenteric infection. Infections from this intestinal source are not infrequently causes of arthritis. When diverticulosis has once developed, great care should be exercised to avoid excess of food, irritating foods and foods containing small sharp seeds. The bowel should be kept empty and harmful bacteria reduced to a minimum. Enemas and careful manipulations should be used to free the diverticula of stercoroliths, foreign bodies and bacteria. Uncomplicated diverticulosis is not incompatible with comfort and good health. Diverticulosis favors the development of intestinal and diverticular flora which invade the intestinal wall and may pass through it, resulting in peritoneal and other infections, or may be picked up by the blood or lymph streams and may be the source of arthritis. Diverticulosis and moderate forms of diverticulitis and peridiverticulitis, and even paradiverticulitis may be treated by nonsurgical methods. Surgery may be required to combat complicated conditions. One may reasonably expect to see surgery grow in favor for the less severely complicated cases as one's understanding increases, yet at present caution and conservatism are the watchwords, and one must be sure that the patient will stand the operation.

Posttraumatic Osteoporosis—Fontaine and Herrmann review the literature on the treatment of posttraumatic osteoporosis and report the results that they obtained in treating their twenty-two patients. They conclude that posttraumatic osteoporosis is a disease entity with characteristic roentgenologic changes in the three main stages of the evolution of the disease. The posttraumatic osteoporosis which is left untreated usually results in an ankylosis of one or more of the joints in the region of the porotic bones. Operations on the sympathetic nervous system offer a rational and effective surgical treatment for this disease entity. Cases of posttraumatic

osteoporosis treated by sympathectomy during the initial stages of the disease respond quickly and the undesirable sequelae of the disease are prevented. Periarterial sympathectomy is usually sufficient for cases of posttraumatic osteoporosis when it is limited to the distal part of the extremities. Cervical and lumbar sympathetic ramisection should be reserved for the extensive forms of the disease.

Irradiation in Carcinoma of Breast—Kaplan and Rosh report the results of irradiation and surgery in 270 cases of cancer of the breast that they treated from 1924 to 1930. In their service they have found postoperative irradiation of value in prolonging the life of the patients and in preventing recurrences. Radiation therapy alone has proved of value for inoperable cases and in several chosen operable ones. Judgment in choosing cases and proper technic in treatment are essential for attaining good results. The technic that they believe will give the best results is a combination of external irradiation over the local area involved and the adjacent lymphatic drainage tissues, together with interstitial treatment with properly designed and filtered radium needles or tubes, as described by Kaplan, by Adair, and by Lee and Pack. As in all surgical procedures, the technic employed must be scientifically carried out by those trained in such work, mediocre attempts at irradiation are as harmful as mediocre surgery.

Partial Hysterectomy and Use of Uterus Stump—LaRoque describes an operative procedure for the relief of cystocele which is as follows. The cervix is pulled down in the usual way and amputated nearly up to the internal os with an electric cautery knife. The cervix is held steady. The vaginal mucosa is divided from a point three-fourths inch behind the meatus almost to the point of cautery amputation. The vaginal mucosa is dissected off around to the side. The bladder is pushed up by a gauze covered finger and with the aid of scissors and pushed upward until the peritoneum comes into view. The peritoneum is divided in the usual way, and the fundus is caught either with the finger or a tenaculum and pulled into the vagina as traction is released on the cervix. A large or small piece of the uterus is excised, including the fundus and all the endometrium, leaving only enough uterine wall to bring together by suture and place under the bladder for support. The edges of the uterus are held in neat apposition with mattress sutures. The stump of the small piece of remaining uterus is interposed between the bladder and the vagina. For this purpose the figure eight stitch prevents bleeding and subsequent accumulation of blood in the space after operation. Finally, the edges of the incision in the vagina are brought together by interrupted sutures. Perineorrhaphy is then performed. The author has performed this operation for varying degrees of prolapse in women ranging in age from 36 to 65 years. The appearance at the conclusion of the operation and nearly a year later has been satisfactory.

Pilonidal Sinus—Weinstein's suggestions for permanent removal are based on thirteen cases in which operation was performed by him. The differentiation of pilonidal sinus from fistula-in-ano is readily made by the absence of granulation tissue and the upward direction on probing. Pilonidal sinus is a special local downgrowth of epithelium, originating from the true skin. A large section of the tissue with a broad base and narrower superficial skin surface will help to prevent recurrence. If necessary, periosteum of the sacrum and coccyx, and gluteal fascia are removed when involved. No attempt should be made to eliminate dead space completely. Local infiltration anesthesia is induced with 1 per cent procaine hydrochloride with epinephrine chloride. The ischemic field produced permits easy recognition of the outermost regions of the lesion. An elliptic incision is carried well beyond the sinus opening and all scars of previous operations, extending through the skin and into the subcutaneous adipose tissue. The scalpel is then tilted at an angle to undermine the skin and a thin layer of fat, for a distance of from one-half to three-fourths inch. Further dissection is performed in an oblique plane so that the base of the excised tissue is much larger than the superficial skin covered portion. In the deep aspect of the wound the dissected mass is stripped from the periosteum of the sacrum and coccyx in the midline and on the sides from gluteal fascia covering the gluteal muscles. From four to five tension sutures of the Stewart

type coapt the skin and grasp a portion of underlying subcutaneous tissue. A small cigarette grain is placed in the lowermost angle. No attempt is made to approximate subcutaneous tissue, gluteal fascia or muscles, as individual layers.

Variations in Skin Anesthesia—Wilkins and Sachs record a series of twenty-six cases in which a section of the posterior root for trigeminal neuralgia was done and in which the sensory loss has been atypical. The portion of the posterior root carrying the ophthalmic fibers is frequently not a separate bundle of fibers. The authors' work confirms that of Frazier and Whitehead that the arrangement of fibers in the posterior root varies and that the fibers interlace or cross. Though some fibers were left in areas in which the patient had pain, the fibers to the area in which the "trigger zone" existed were always cut, and only one of their patients has had a recurrence, thus far, as a result of leaving some fibers. This may mean that some of the pain in cases of trigeminal neuralgia is referred pain. This view has been expressed frequently in regard to the pain in the first division of which patients complain, and it may also be true of pain in the other divisions.

Status Marmoratus—Löwenberg and Malamud present four cases, in three of which postmortem examinations showed, among other lesions, the presence of status marmoratus, in the fourth case the clinical picture and history were typical of the syndrome of status marmoratus. In the authors' cases the important features were as follows: 1. There was a negative family history and a normal interval between birth and the onset of the disease. 2. The clinical history of the onset of the disease and the histologic picture showed that the disease developed on the basis of an encephalitic process, most probably acquired. 3. The involvement was widespread, affecting the cortex as well as the basal ganglia, while in one of the cases the status marmoratus was present in the cortex and not in the ganglia. They conclude that, in view of their observations and a number of similar data reported by other observers the original concept of the nature of this disease will have to be revised.

Amyotrophic Lateral Sclerosis—Hassin reports in detail the case of a man, aged 48, who entered the Cook County Hospital because of inability to walk and rigidity of the left upper extremity. A study of the pathologic data justified a diagnosis of amyotrophic lateral sclerosis complicated by a degeneration of a sensory tract of fibers, the columns of Goll, and, to a lesser extent those of Burdach. The author concludes that amyotrophic lateral sclerosis essentially a motor nerve disorder clinically may show sensory disturbances. Pathologically, it may be associated with degeneration of the sensory tracts suggesting a combination with subacute combined degeneration of the cord. From the extent and intensity of the degeneration, one may assume that one morbid process arises after the other both being caused by the same as yet unknown factor. The basal portions of the posterior horns of the gray matter of the spinal cord may be a part of the patho-

logic picture in atypical cases of amyotrophic lateral sclerosis and be responsible for the subjective and objective sensory disturbances occasionally observed in this morbid condition.

Experimentally Produced Convulsions—Of the various acetone bodies tested, Keith observed that aceto-acetic acid and its sodium salt have the most pronounced effect in preventing thujone convulsions, experimentally produced in rabbits. The injection of acids (acetic, lactic, citric and hydrochloric) as such and of sodium pyruvate has a definite anticonvulsant effect under the conditions of the experiment but they are less effective than aceto-acetic acid. Epinephrine, solution of pituitary double U. S. P. strength (surgical) and ampoules of pitressin greatly augment the convulsant action of thujone and the action of epinephrine, and pitressin persists for at least three minutes after intravenous injection. These drugs will cause a subconvulsant dose to become convulsant. Epinephrine eliminates the refractory period due to the administration of thujone. The administration of desiccated thyroid and thyroxine did not definitely increase the susceptibility of the rabbits to convulsions produced by thujone. The administration of insulin to rabbits with resulting hypoglycemia did not increase their susceptibility to convulsions. Large amounts of water by stomach tube, either alone or accompanied by intramuscular injection of pitressin may possibly increase the animals' susceptibility to convulsions produced by thujone. There was a slight increase in the amount of water in the tissues of the brain of animals receiving pitressin.

Erysipelas of Pharynx and Larynx—Katz points out that erysipelas of the pharynx and larynx presents a definite clinical and pathologic entity a diagnosis of which can be made without manifestations on the skin. If acute edema of the pharynx or larynx develops, with fever and general malaise, subsequent to or during acute tonsillitis or a cold the disease should be considered as erysipelas, if streptococci are the causative germ. The milk-borne epidemics of sore throat were definitely reported by some as epidemics of erysipelas of the pharynx and larynx. The so-called septic sore throat, considered from the standpoint of the source of infection, manner of transmission, complications and bacteriologic resemblance, is identical with erysipelas of the throat. Treatment in addition to symptomatic measures, should include serum and vaccine therapy.

Primary Jugular Bulb Thrombosis—Maybaum and Goldman observed, in a study of twenty cases of primary jugular bulb thrombosis over a period of eleven years, that certain anatomic factors, such as a thin bony partition separating the middle ear from the bulb, a high dome and dehiscences, predispose to involvement of the bulb. In children or young adults with a history of an acute infection of the middle ear, a fluctuating fever, a progressive anemia, changes in the ocular fundi and evidences of a general infection otherwise unaccounted for, primary jugular bulb thrombosis should be suspected. The additional presence of a positive blood culture establishes the diagnosis. A majority of the cases follow a characteristic course, suggesting a clinical entity. Blood culture studies are of paramount aid in diagnosis. Those that the authors took before operation (nineteen of the twenty cases) were positive for *Streptococcus hemolyticus*. The following conditions must be considered in the differential diagnosis: acute tonsillitis, pneumonia, erysipelas, acute naso-

pharyngeal infections and pnelonephritis. In the surgical treatment, occlusion of the main channels of systemic invasion especially of the torcular end of the diseased sinus, is of prime importance. An operation on the jugular bulb should be performed only if there is a continuance of bacteremia and symptoms general or local, after the main channels have been obliterated. Extensive operations on the jugular bulb are seldom indicated. For a favorable outcome early diagnosis and prompt surgical intervention, properly directed are imperative.

Juvenile Dementia Paralytica—Polmer reports the case of a boy, aged 12, presenting diagnostic criteria of juvenile dementia paralytica, in whom vigorous antisyphilitic treatment and malarial therapy were employed for eleven months without any subjective improvement or sufficient objective laboratory signs to warrant a diagnosis of an arrested case or a remission. After the administration of twelve diathermy hyperpyrexia treatments over a period of six weeks the spinal fluid of the patient was serologically negative on two successive examinations, repeated ten days apart. The patient was discharged as improved seven weeks after the series of treatments were begun.

Exophthalmic Goiter—Bram discusses 220 cases of exophthalmic goiter without an increase above the conventional normal basal metabolic rate and without loss in weight. Of these patients, 74 were untreated, 8 had cases of protracted duration with so called 'burned-out thyroid' 12 had been treated with iodine preparations prior to coming under the author's observation 117 had undergone subtotal or total thyroidectomy and 9 had received excessive roentgen treatment. The data derived from these cases appear to indicate that a high metabolic rate is not imperative in the diagnosis of exophthalmic goiter. It appears that the disease is not synonymous with hyperthyroidism and that the syndrome may occur without demonstrable thyroid excitation.

Glycerin Extract of Suprarenal Cortex Potent by Mouth—Hoskins and Freeman treated ten schizophrenic

patients, initially presenting low blood pressure for ten weeks with glycerin extract of suprarenal cortex. The dosage was gradually increased from an equivalent of about 100 grains (6.5 Gm) to 450 grains (29 Gm) of fresh gland substance daily. The systolic blood pressure was increased in all cases. The average initial pressure was 105.7 and the final pressure 132.5 mm of mercury. Similarly, the diastolic pressure was increased from 69 to 84 mm. The blood pressure returned to approximately the initial levels after the treatment was discontinued. There was an irregular increase in the weight from an average of 62.6 Kg at the beginning to 65.4 Kg at the end. There was also a fairly consistent increase in the red cell counts of about 300,000 on the average in each case. At the end the increase had fallen to about 150,000 cells above the initial level. There was evidence of early stimulation of the renal function with a later return toward initial levels. There was an apparently significant increase in the oxygen consumption rate but this was not sustained. There was a slight downward trend in the nitrogenous bodies of the blood.

Electrocoagulation of Vascular Tumors—Tyler states that vascular tumors that cannot be removed with the sharp scalpel can be readily removed by electrocoagulation. By employing his specially designed technic the operation can be bloodlessly and rapidly done. He uses two pointed active electrodes instead of one active and one inactive electrode as is generally done. He places the two electrodes in contact with the tissue about 1.5 cm. apart, and the high frequency current is thus short circuited between them. In this manner the intense heat generated between the two electrodes is sufficient to coagulate blood in large vessels and vascular spaces before the walls are opened. In this way the tissue is not separated until after it has been coagulated, and no bleeding occurs. In cases in which the shape of the tumor lends itself to amputation, a line may be coagulated across the base. This is accomplished by holding the two electrodes in contact with the tissues at one place long enough to coagulate the tissue between them and then moving to the next area. The author has also applied his technic in lobectomy of the lung. This technic makes the removal of the lobe bloodless and expeditious. One must thoroughly coagulate the bronchus and vessels before pulling the lobe away from its attachment. This type of coagulation can be done only with a current of from one million to one million eight hundred thousand frequencies per second. The higher frequencies cut too much and coagulate too little. The advantages of electrocoagulation by his technic are accuracy of control, no bleeding, absence of pain, absence of afterpain and little scar tissue.

Tumors of Breast—In his study of tumors of the breast Davis concludes that the breast is practically devoid of lesions before puberty. A solid freely movable tumor between the ages of puberty and 25 is most likely a fibro adenoma and especially so if multiple. If single, one must suspect carcinoma and excise the tumor at once, rather than waiting to see if it will grow. Diffuse painful breasts, with the pain accentuated before menstruation and with no definite lumps but only a diffused nodularity that is tender, is probably mastoplasia. It is a physiologic process is not surgical, has no serious sequelae and is treated by ovarian residue. If multiple

nodules appear, especially after the age of 25, it is most likely cystiphorous desquamative epithelial hyperplasia, which is of importance because it may become carcinomatous. These cysts are differentiated from solid fibro-adenomas by transillumination. If the cyst is single it should be excised and if multiple mastectomy should be done. Bleeding from the nipple indicates most commonly papilloma or carcinoma. If unassociated with a lump, it is probably the former. However, owing to its malignant tendency it should be excised and, if multiple, the entire breast should be removed. Retraction of the nipple is most commonly congenital, follows an acute inflammation of the breast or is due to carcinoma. If it has developed recently in a middle aged or elderly woman a radical mastectomy should be performed. Any single painless lump of the breast should be considered as cancer until proved otherwise, and immediate biopsy should be advised.

Neurodermatitis and Lichenification—Ormsby states that prurigo nodularis (lichen obtusus corneus) is an entity and unrelated to lichen planus. Sufficient evidence has not as yet been presented to place the disorder as a nodular variety of lichenification. A chronic itching papular eruption of the axillae and pubes (Fox-Tordyce disease), originally considered a variety of neurodermatitis, is excluded from this group and should be classed as an entity. Giant or hypertrophic lichenification may be employed to designate those cases in which the process of lichenification is excessive and unusual lesions are produced. Verrucous lichenification as described by the author includes lichen planus hypertrophicus and lichen planus verrucosus of the English authors or hypertrophic lichen corneus or lichen verrucosus of the French. Some of these cases occur independently of lichen planus. Lichenification is an important factor in these lesions. There is no objection, therefore, in placing the group as examples of verrucous lichenification. Lichen planus hypertrophicus and verrucosus however should retain their positions as varieties of lichen planus. The term neurodermatitis should be applied and limited to the disorder described by Vidal as lichen simplex chronicus and by Brocq as neurodermatitis circumscriptus et diffusus or circumscribed pruritus with lichenification and diffuse pruritus with lichenification. The mosaic thickenings induced by scratching and rubbing in eczema, sensitization dermatitis, mycotic infections, lichen planus, scabies, prurigo, mycosis fungoides, leukemia, and lymphogranulomatosis should be recognized as secondary lichenifications quite distinct from neurodermatitis. The author concludes that, as neurodermatitis frequently occurs in neurotic persons an exhaustive search should be made to determine the provocative factors relating to these symptoms, and measures should be taken for their relief. In the localized patches roentgen rays cautiously employed are of much value. Crude coal tar with Burow's solution has been of much service. Tricresol from a 25 per cent to a full strength solution for localized patches in the scalp originally suggested by Stillians is of great service. The internal administration of arsenic is valuable but should be done with all proper precautions.

Diet in Disease—Ervin discusses in a general way the question of diet in disease. The public, as a whole, seems to expect dietary restrictions in all manner of disease irrespective of the nutritional requirements, and the profession has had a tendency to court the idea rather than to follow the best professional judgment. The author believes that both the public and the profession should share the responsibility of improper

nutrition in disease. There is no advantage in the customary protein restriction in nephritis. In fact the patients do better on a liberal intake of food including protein. He emphasizes the increased caloric requirements brought about by fever and gives the dietetic requirements in some nonfebrile diseases such as thyroid dysfunctions, gout, peptic ulcer and hypertension. The patient's appetite is the most valuable guide in determining what to give. The patient usually knows what his stomach will tolerate.

Infiltration Anesthesia in Obstetrics—Greenhill presents a technic of local anesthesia which is indicated in dilation and curettement, spontaneous delivery, episiotomy and repair, suture of both recent and old lacerations, low forceps operations, cesarean section (both classic and cervical), Porro hysterectomy, anterior vaginal hysterotomy (vaginal cesarean section) and sterilization (both abdominal and vaginal). Because direct infiltration anesthesia is so much safer than all the other forms of anesthesia and so simple to use it should be employed oftener than it is at the present time. There is no doubt that the increased use of local anesthesia will help to reduce the appalling number of unnecessary maternal deaths. His technic is as follows: In nearly all cases, his patients are given a hypodermic of $\frac{1}{4}$ grain (0.016 Gm) of morphine and $\frac{1}{500}$ grain (0.0003 Gm) of scopolamine fifteen minutes before the infiltration of the local anesthetic is begun. The patient should be made as comfortable as possible during the operation. For the local anesthetic he uses a 0.5 per cent solution of procaine hydrochloride, although a 0.25 per cent solution is almost as effective. To this solution after sterilization he adds 2 drops of 1:1,000 epinephrine for each ounce. The amount of solution he makes depends on the type of operation to be performed. For small vaginal operations, such as episiotomy, repair of lacerations, dilation and curettement and low forceps operations, not more than 4 ounces (120 cc) is necessary. For cesarean sections between 6 and 8 ounces and in Porro operations between 8 and 10 ounces is necessary.

Treatment of Carcinoma of Lower Intestine—Babcock states that carcinomas of the large intestine should be diagnosed early by the change in peristaltic activity, by melena and by digital, proctoscopic and roentgen examinations. Offensive, bloody, mucous stools or intestinal obstruction usually indicate a growth of long standing. Operative excision, if the growth is not too far advanced, gives reasonable hope for recovery. From the ileum to the midsigmoid an intraperitoneal or exteriorization, excision and anastomosis, with careful attention to the blood supply to the retained bowel is the preferred type of operation. From the midsigmoid to the lower rectum, a combined abdominoperineal operation is preferred as permitting thorough exploration followed by radical removal of the involved segment of bowel with the tributary lymphatics as well as the preservation of an adequate circulation for the retained intestine, which cannot be obtained by the perineal operation. The author describes a simplified method of abdominoperineal resection in which colostomy is eliminated and the bowel is not divided or invaded until after the peritoneal cavity is sealed. With the higher rectal growths, the sphincters may be preserved, with the lower ones a wide resection of the pelvic floor is necessary. In the cases in which he has used this operation, less shock and reaction have followed than after any radical type of operation the author has tried. The mortality in nonselected cases has been about 10 per cent. For the small, low-lying rectal carcinomas, with low infiltrative tendencies, a wide local excision through the enlarged anus may at times be adequate. He has had no experience with the metastases from anal growths to the inguinal lymphatics as described by Miles, but this possibility should be considered if the growth involves the sphincters. A properly made and sufficiently large perineal anus may be cared for with less derangement of the clothing than a colostomy and is easily controlled by a pad. The perineal opening also gives a better warning of an impending defecation than does the colostomy, and by digital examination one may obtain early evidence of a recurrence in the pelvis at a time when it may be effectively excised or destroyed.

Diagnosis and Treatment of Diaphragmatic Hernia—Hedblom points out that thoracic symptoms and signs of diaphragmatic hernia may include substernal pain, dyspnea, cyanosis, palpitation, a feeling of oppression or of suffocation, dextrocardia and variable abnormal signs on percussion and auscultation. Abnormal symptoms and signs are chiefly such as are suggestive of mild gallbladder disease or of peptic ulcer and those of partial or complete obstruction often without abdominal distention. Positive diagnosis rests essentially on the roentgenologic demonstration of abdominal viscera in the thorax following contrast mediums or enemas. Abnormal shadows in the ordinary roentgenogram may be suggestive. Negative roentgenologic observations may be due to temporary reduction of the hernial contents. Operation for repair may be through a laparotomy or thoracotomy approach, or through a combination of the two. In the majority of cases the hernia

may be reduced and repaired by any one of these routes. There are special advantages, limitations and indications for each, depending on the anatomic and clinical type of hernia. Special procedures for the closure of large or recurrent hernias include muscle and fascia plastic operations, shifting of the attachment of the diaphragm and thoracoplasty in special cases. Differential pressure anesthesia is essential to obviate the dangers of open pneumothorax during operation, and inflation of the lung before closing the pleural cavity and aspirating the air later to restore the normal vital capacity of the opposite lung and to reinflate the lung on the side of the hernia. Respiratory insufficiency, especially in infants, intestinal obstruction and postoperative shock are the most common causes of death.

Complicating Lesions of Appendicitis—According to Royster, first and foremost of all the complicating lesions of appendicitis stands peritonitis. It follows directly on perforation or gangrene of the appendix. The upper abdominal conditions most frequently associated with a pathologic appendix are gastric and duodenal ulcer, gallbladder infection and pancreatic disease. They constitute a vicious circle. Undoubtedly long continued infection of the appendix may lead to definite pathologic changes in the liver, infiltration around the radicles of the portal vein with degeneration of the cells and in the chronic or more severely acute forms infiltration also around the biliary radicles with surface markings of interstitial hepatitis. Inflammation of the portal vein or any of its branches is always a serious complication, and usually fatal. Unless thrombi or abscesses occur, there may be some hope. A quieting complication is a subdiaphragmatic, or subphrenic, abscess. Acute gangrenous or suppurative appendicitis is responsible for the great majority of the cases. The abscess rarely forms before the eighth or tenth day. In toxic appendicular nephritis the only sign is albuminuria, seen in the rapidly progressive types of acute appendicitis and disappearing promptly after operation. There is no general edema and the albumin may be scanty. Hemorrhages from the stomach, genito-urinary tract or the intestine if not due to associated organic diseases in the regions named, must be regarded as toxic in origin. Hematemesis may be a part of the toxic syndrome of appendicitis, most frequent in the so-called chronic type, but seen at times in the acute types, especially of the gangrenous form. Hematuria is not uncommon in cases of appendicitis associated with acute hemorrhagic nephritis, and in cases of contact—an inflamed appendix adherent to the kidney, ureter or bladder. Bleeding from the bowels may accompany appendicitis complicated by diarrhea with mucous discharge or come from a toxic ulceration of the colon in the form of copious hemorrhages. The author concludes that the pathologic complications of appendicitis may themselves prove to be more troublesome and more deadly than the local lesions in the appendix. The possibility of their occurrence and the realization of their danger must be kept in mind. It is the complications that kill.

Calcified Abdominal Lymph Node—Occasionally one wishes to distinguish between a stone in the midportion of the ureter and a calcified lymph node in the abdomen without ureteral catheterization. Floyd and Pittman have recently devised a method to do this in selected cases. A roentgenogram of one of their patients showed a shadow, about 1 cm in diameter, just below the crest of the ilium in line with the right ureter. A second roentgenogram was taken after pushing the abdominal contents over and holding them in place with both hands. This showed the shadow, along with others on the opposite side of the spinal column, demonstrating that it was not a stone in the ureter but most likely a calcified node in the abdominal cavity. At operation the authors found an acute exacerbation of a chronically inflamed appendix and calcification of the ileocolic lymph nodes.

Phagocytic Reaction in Hay Fever.—In the course of examining films of *Phleum pratense* pollen stained with iodine, Harley observed a granular appearance of the substance of the grain. He prepared suspensions of these granules for phagocytic tests. The phagocytic index was determined in twenty-four normal and non-hay fever patients and in twenty-five hay fever cases. "Chiastic" counts were made in five cases. In twenty-three of the twenty-four non-hay fever bloods nearly all the granules were found to have been dissolved, the few remaining being recognizable inside the leukocytes. The phagocytic index was low, the average being 0.4. In twenty-two hay fever cases the index was comparatively high, and in addition there were certain numbers of granules unphagocytosed, the average index was 2.4. In three cases the indexes were normal or only slightly raised. The high indexes were from severe hay fever cases, but the converse did not always apply. All hay fever patients gave positive skin tests to *Phleum*, *Dactylis* and *Holcus*.

Ovarian Endothelioma and Monocytic Leukemia.—Gittins and Hawksley describe in detail a case of bilateral ovarian endotheliomas in an infant aged 1 year. This resembled a reticulo-endotheliomatous process not heretofore recorded. The neoplasms though extirpated were followed by general reticulo-endotheliosis with the blood picture of histiocytic leukemia and a high lymphocytosis of normal type. In reviewing the literature the authors observed that endothelioma of the ovary is a rare condition and several varieties are recognized, their case being somewhat different from those previously recorded. Including the one they describe only twenty histologically authenticated cases of monocytic (histiocytic) leukemia are reported. The observation of focal neoplasia (ovarian endotheliomas) and general (histiocytic) leukemia in the same patient within a few weeks is offered by the authors as evidence of the essentially neoplastic nature of this type of leukemia.

Sarcosporidiosis in Cardiac Muscle.—Hewitt describes the histologic features of a specimen of normal cardiac muscle observed at the postmortem examination of a young woman who died as the result of an accident. After routine fixation in tap water formaldehyde the pieces were stained in bulk with Ehrlich's hematoxylin counterstained with eosin dehydrated, cleared, and embedded in paraffin. When the author had occasion to employ the material for teaching purposes, he noted the presence of abnormal structures. They were recognized as a sarcosporidial infection. The principal features were (1) heavy infection in true muscle and in Purkinje's tissue (2) uniformity in the size of the cysts (3) well marked delimitation of the cyst wall into layers (4) profuse trabeculation dividing the cyst into loculi, (5) presence of a few sporoblasts peripherally and many spores centrally (6) absence of degenerative changes toward the center of the cyst, (7) semicircular shape of the spores, (8) presence of a nucleus and a doubtful nucleolus, (9) presence of acidophil and basophil granules, these being generally situated terminally, (10) normality of the surrounding cardiac muscle, and (11) normality of the adjacent Purkinje's tissue.

Tuberculosis with Bovine Type of Bacillus in Sputum.—Cumming and Foster present their method for the isolation and identification of tubercle bacilli of the bovine type from fourteen cases of pulmonary tuberculosis. It is as follows: A morning specimen of sputum is collected and an equal quantity of one normal sodium hydroxide solution is mixed with it for thirty seconds and centrifugated at 2,000 revolutions per minute for twenty minutes. If the specimen is more than usually

viscous, the mixture is incubated at 37 C for twenty minutes before centrifugating. The supernatant fluid is decanted the deposit is then roughly neutralized with three or four drops of normal hydrochloric acid solution, mixed and seeded on four slopes of egg medium. The tubes are incubated, examined weekly and discarded in three months if no growth is obtained. In the few instances in which the sputum is 'positive' on microscopic examination and yet no growth is present or in which although microscopic and cultural examinations are negative the clinical evidence strongly suggests that tubercle bacilli may be present in small numbers the reverse method of concentration is employed, hydrochloric acid being used as the concentrating reagent and sodium hydroxide for neutralizing. From the 384 cases of pulmonary tuberculosis, twenty-two bovine strains were isolated. In any given case of pulmonary tuberculosis, the presence of tubercle bacilli of the bovine type seems to be of definitely unfavorable prognostic significance. The authors point out that the possibility of the occurrence of human-to-human and of human-to-bovine infection with the bovine type of the tubercle bacillus becomes increasingly more difficult to ignore. At the necropsy in two of the cases they observed that the route of infection was alimentary and that the lung lesion was indistinguishable from that due to the human type.

Migraine—Critchley and Ferguson state that migraine may be due to bilious, ocular, menstrual, cerebral or allergic factors. Despite an immense amount of research the essential causation remains obscure. It seems certain that there must be at least two factors "central" and "peripheral." They are inclined to regard migraine as a vasomotor manifestation associated with spasm of the cerebral arteries most commonly the branches of the internal carotid due to stimulation of the sympathetic fibers either as the result of direct pressure or by way of the endocrine system occurring in a susceptible person with the migrainous constitution and with precipitating factors. Success in treatment will depend on the ability to place a particular case of migraine in its proper category and to apply the appropriate remedy. The complete investigation of a patient with migraine will include (1) a careful previous and family history and a minute study of the symptomatology (2) physical and psychologic examination (3) careful testing for ocular abnormalities, (4) roentgen examination of sinuses, sella turcica, gallbladder and gastro-intestinal tract (5) full examination of the cerebrospinal fluid including pressure readings (6) biochemical investigations (blood sugar estimation, urine, alkali reserve) and (7) basal metabolic rate investigation. It is useless to try to fight off an attack therefore the authors recommend retirement to a quiet darkened room as soon as possible, and the administration of 6 grains (0.4 Gm) of an amidopyrine-barbital preparation repeated in half an hour or 15 grains (1 Gm) of acetphenetidin and 5 grains (0.3 Gm) of caffeine citrate to be repeated, if necessary, at hourly intervals for three doses. Between the attacks some cases may be suitably treated with magnesium sulphate, dextrose and bile acids, theelin, thyroid special diet or psychotherapy. For the severe cases that do not respond to conservative measures, the authors recommend a right subtemporal decompression.

New Form of Bed Tent for Administering Oxygen and Carbon Dioxide. E P Poulton with account of clinical oxygen measuring pipet by E P Poulton and J W Shackle—p 244

Treatment of Burns—Mitchiner points out that, under the old bath and grease treatment, the average mortality was 396 per cent for burns and 188 per cent for scalds. In the early days of the trinitrophenol treatment the mortality was 397 per cent for burns and 7 per cent for scalds, and in the last five years of the trinitrophenol treatment the mortality was 155 per cent for burns and 75 per cent for scalds, whereas the adoption of tannic acid in October 1928 and its systematic use in subsequent years has reduced the mortality to 4 per cent for burns and 17 per cent for scalds. The author adds that during the period from 1929 to the present time, when tannic acid compresses have been used as the routine outpatient treatment for all burns and scalds, no deaths have occurred among the slighter cases, which average 800 a year and of which about one third are children under 10 years of age. There is, however, a seasonal incidence of approximately 3-2 during the winter months. The treatment of burns and scalds, following adequate cleansing of the damaged area aims at lessening collapse by stopping the absorption of the bodies that cause this collapse and death in from twelve to forty-eight hours after the burn, and also at diminishing the loss of fluid from the burned area which is so serious and so often fatal in the first six to twelve hours. A further aim is the prevention of toxemia from absorption of septic material from the infected burned area which may be manifested elsewhere, especially as septic bronchopneumonia and cause death in from five to twelve days. The initial shock and suffocation cannot be affected by local treatment of the burned area, and the percentage of death from these causes can be ameliorated only by efficient first aid treatment by those present at the time of injury. The author believes that a stock solution of 2 per cent tannic acid and 1/2,000 corrosive mercuric chloride adequately fulfils the needs of the compress method. In order to meet the desirability of applying this solution warm to the burned area it is his custom to keep it in a concentrated form and dilute it with the requisite amount of warm water. He does not advise keeping it at more than double strength as he finds that more concentrated solutions are inclined to decompose more quickly and the results obtained are therefore not as painless or as satisfactory as those given by the weaker solution. In order to meet the requirements of shops and the home, where burns are not frequent, he compounded a tablet containing 17½ grains (1.14 Gm) of tannic acid, ½ grain (0.032 Gm) of corrosive mercuric chloride and 1 grain (0.065 Gm) of boric acid (excipient) which tablet dissolved in 2 ounces (60 cc) of water gives a solution of the necessary strength though slightly muddy in appearance owing to the presence of the boric acid which however does not interfere in any way with its efficacy of coagulation. It can be used equally well for spraying when this method is preferred.

Purpura in Childhood—Witkin points out that primary purpura is an uncommon disorder of childhood. In seven and a half years only eight cases were recorded in the Transvaal Memorial Hospital for Children. The sex incidence was equal. The etiologic factor is still unknown. Probably there is some bacterial or biochemical agent acting on the thrombopoietic system and endothelium of the capillary walls. A blood count

and Wassermann test should precede all other investigations. The diagnosis of purpura hemorrhagica is made on a history of recurrent hemorrhages, a low platelet count, prolonged bleeding time, and delay in clot retraction. The treatment is mainly symptomatic. Drugs are on the whole disappointing. Of these, epinephrine is one of the most valuable. Every effort should be made to eradicate a septic focus. The mild cases recover promptly with rest, avoidance of exposure and injury. Protein therapy, blood transfusions, serum therapy and roentgen irradiation of the spleen have but a limited sphere of usefulness. Splenectomy is the treatment *par excellence* in the chronic recurrent types. The author reports one case of splenectomy. Ligation of the splenic artery is the operation of choice in the severe acute forms, in which splenectomy may terminate fatally.

Muscular Extracts in Cardio-Arterial Therapy—After reviewing briefly the various trends of investigation concerning so-called cardiac hormones, substances regulating the cardiac automatism, Deschamps discusses the cardiovascular action of the extracts of peripheral muscles which have been prepared notably by Schwartzmann and by Fahrenkamp and Schneider. These extracts act less on the heart than on the vessels, especially the coronary vessels and their action is above all vasodilatory. They constitute a medication for arterial spasms and its manifestations, essentially for angina pectoris and intermittent claudication from thrombo-arteritis and in a measure, hypertension. The best results are obtained in the particularly spasmodic forms of angina pectoris, while forms in which organic changes dominate, especially cardiac insufficiency with dilatation of the heart or coronary thrombosis, give uncertain results or none at all. According to Drucker the extracts are indicated in the so-called ambulatory forms, in which walking is suddenly arrested by violent retrosternal oppression while the collapse and anguish are often lacking, the toxic forms and the vasomotor forms. In addition to their vasodilatory and antispasmodic action, some authors claim a cardiotonic and cardioregulating action for these extracts. Favorable results have been reported especially in cardiac decompensation and arrhythmia. The author compares the action of these extracts with digitalis and with hepatic and pancreatic extracts. The muscular extracts are usually administered orally but may be given intramuscularly, they have been given intravenously, primarily for disturbances of rhythm. Investigations indicate that the active substances in the muscular extracts are probably proteins similar to amino acids. Adenine nucleotides, adenine pentoside and adenosine triphosphoric acid are among the substances that have been isolated from the extracts by various authors.

Recent Changes in Preparation of Condensed Milk G. Blechmann—p. 101

Prandial Diarrhea in Breast-Fed Infants—Marfan discusses prandial diarrhea of breast-fed infants. Its distinguishing characteristic is the evacuation of stools toward the end of or immediately after each feeding. It usually starts in the first two weeks and recedes spontaneously about the fourth month. The stools are usually mucogrumose but may become liquid both of which have a normal odor and reaction. Frequent eructations and regurgitations occur in prandial diarrhea and sometimes the evacuations are preceded by slight colics. In the severe forms the nutrition and weight increase may be disturbed. There are no serious complications. Prandial diarrhea is practically limited to breast-fed infants. It is not due to the bad quality of the milk ingested but to a special sensi-

tivity of the infant's digestive tract to all human milk, to that of certain women (usually including its mother), or to that of its mother only. When the milk enters the stomach and the duodenum, exaggerated duodenobiliary and gastrocolic reflexes are produced and the violent peristaltic contractions result in an evacuation of the intestine. This special sensitivity is attributed by Alarcon to an exaggeration of the hyper-vagotonia of the new born by Weill to an anaphylactic state. The first step of the treatment should be to ascertain that the nursing periods are well regulated and that the mother's diet is correct. In the light forms nursing at the breast should be continued and belladonna and bismuth subnitrate administered to calm the hyperexcitability of the digestive tract. A daily enema with a warm decoction of marshmallow root with a half teaspoonful of sodium bicarbonate is advised. In severe forms or in forms that persist despite this treatment the same medication should be given and in addition mixed feeding should be instituted. If the infant is less than 2 months of age, one breast feeding daily is replaced by a bottle of unsweetened buttermilk or unsweetened condensed milk if the improvement is not sufficient, two breast feedings may be replaced by bottles. If the nursing is more than 2 months of age, the buttermilk or condensed milk is diluted with a decoction of rice instead of pure water. When the diarrhea disappears exclusive breast feeding may be resumed. If it reappears, one may return to mixed feeding. It is rarely necessary to replace breast feeding entirely by artificial feeding and it should be deferred as much as possible.

Infection in Nurslings—In a general discussion of infections in nurslings Ribadeau Dumas and Rault state that they are usually represented by a triad of symptoms always present in varying degrees: modifications of the thermal curve of the weight curve and of the stools. In the nursling the first infection is always benign. It is marked by a general slight thermal elevation, arrest of growth and slight digestive disturbances. This syndrome is reproduced at the moment of reinfection, but it is always much more pronounced. At this point the drop in weight more than the degree of fever indicates the gravity of the infection. The severity of the syndrome of reinfection depends on the degree of passive immunity transmitted by the mother or of acquired immunity of the nursling. In the course of recurrent infections the temperature and weight curves reach their maximum when the passive immunity is disappearing and the active immunity is beginning to be acquired. This is generally in the third quarter of the first year. The temperature curve, which exhibits higher and longer elevations at each attack or a progressive decrease in the height and duration of the elevations, is a guide to favorable or unfavorable prognosis. The weight curve is even more significant from this point of view. In nurslings one type of infection exhibits many clinical forms, varying from the silent to the gravest forms.

*Treatment of Melitococcosis by Neoarsphenamine J. Vidal—p. 223

Epidemic Megalerythema—Tanon and his associates discuss the differential diagnosis of megalerythema. The erythema makes its first appearance as rose colored macules occurring on both cheeks. These merge so rapidly that the macular stage is often unnoticed and the first sign to attract attention is a diffuse redness spreading over both cheeks. The stage of confluence is followed within a few hours or days by a stage of involution. From one to four days after the appearance of the erythema on the face, it appears on the extensor surface of the forearms, stopping at the wrists but spreading to the upper arms. The buttocks and antero-exterior surface of the lower extremities are also affected the trunk but rarely. The three stages of evolution are best seen on the forearm. The confluence of the macules into erythematous spots of the size of a palm is characteristic of the disease. In the involution stage the spots pale progressively, and often the centers pale while the borders remain rose, producing characteristic circinate figures, which are found in all typical cases of megalerythema.

The eruption may exist in different stages in different parts of the body giving it a polymorphic character. One of its essential features is its alternate attenuation and accentuation. The disease lasts about ten days. It is benign apyretic and without complications, therapy is useless. Megalerythema is distinguished from rubella by the confluence of the macules, the gradual evolution of the erythema and its persistence and reviviscence, the absence of adenopathies and a more benign general condition. Megalerythema may be confused with the erythematopapulous type of erythema multiforme. Erythema multiforme usually starts on the extremities instead of on the face and affects the backs of the hands and feet, its papules being elevated and infiltrated. Megalerythema is contagious and often epidemic, while erythema multiforme is probably not contagious. The only modification of the leukocytic formula in megalerythema is a slight eosinophilia; in rubella there is a hyperleukocytosis and increase in plasma cells while erythema multiforme sometimes shows a slight leukocytosis.

Treatment of Melitococcosis by Neoarsphenamine—Vidal has found neoarsphenamine efficacious in the treatment of melitococcosis six out of eight cases having been favorably influenced by this therapy, one case was refractory to treatment and in one case treatment was interrupted too early to determine the results. At first the neoarsphenamine was administered intravenously in doses progressing gradually from 0.15 Gm to 0.6 Gm given once a week. Later the initial dose was raised to 0.3 Gm and the injections were given twice weekly, the maximum dose often not exceeding 0.45 Gm. The average total dose employed was from 2.5 to 3.5 Gm. Each injection is usually followed by a sudden drop in temperature after which the febrile wave continues at a lower level until the temperature returns to normal. Injections given when the patient is almost apyretic sometimes produce slight thermic elevations (less than 1 degree) which the author regards as reactivation phenomena; they soon disappear. Injections should be continued until a stable apyrexia is obtained. The injections were usually started from one to two months after the beginning of the disease. In all but one case, cure was obtained within from one to three weeks after the first injection, the total duration of the disease varied from thirty-seven days to three months, but usually it was considerably less than three months. In one case it required twenty-five days to bring about defervescence and forty days to bring about complete thermic stability but even in this case the total duration was only two months.

Measuring Labor Pains—Frey and Wenner made observations on twenty-eight parturient women in the Zurich clinic, utilizing Crodol's apparatus for the measurement of labor pains. By means of his apparatus, which is built on the principle of a tonometer, Crodol states that he is able to determine the force of an individual uterine contraction and estimate the working capacity of the uterus. Crodol proceeds on the assumption

that the muscle possesses two properties, stiffening and thickening, appreciable on palpation. Stiffening represents the force and thickening the lifting power. The amount of work the uterus is capable of is represented by the formula: force times lifting power. The authors state that the data obtained by them in the twenty-eight parturient women possessed no clinical value. Four groups were considered separately: (1) primiparas, (2) multiparas, (3) those with premature rupture of the amniotic bag and (4) those without premature rupture of the bag of waters. The authors state that no relationship could be established between the determined contractile force and the number of contractions required in a given case to complete the first or the second stage of labor. Moreover, the method failed to throw any light on the question of the relation between the size of the child, the size of the pelvic outlet or of the cervical canal, and the fact that in one case the stage of dilatation or the stage of expulsion required more contractions than in another. The authors conclude that Crodol's method is of no value in prognosticating the progress of labor.

Liver and Reticulo-Endothelial System After Eclampsia—Dietel and Polak point out that, in the past, studies of eclampsia have been principally concerned with kidney disease. In spite of the manifest importance of the liver in toxemias of pregnancy, this organ has received but little attention. More recent researches have established a pathologic bilirubinemia in acute eclampsia. The finding of a positive van den Bergh sign has been considered indicative of particularly severe damage to the liver. The authors investigated the question of persisting liver damage in post eclamptic women. The following tests were used: (1) bilirubin functional test, (2) levulose tolerance test and (3) the storing capacity of the reticulo-endothelial system for congo red. The Hijmans van den Bergh quantitative test was used and a retention of 15 per cent of the injected bilirubin at the end of three and one half hours was considered pathologic. At the same time an independent study was made of the subjective complaints as well as of the frequency of disorders of the liver and of the biliary tract after eclampsia. A follow-up study was made of eighty-four post eclamptic patients. Of these, twenty-nine were examined; twenty-two made replies to a questionnaire and thirty-three failed to reply. The functional tests demonstrated that the storing capacity of the reticulo-endothelial system remained impaired up to nine years later. Latent icterus was demonstrable six years later, while levulose tolerance remained diminished four years later. These rather frequent observations of liver insufficiency were not demonstrable by urinalysis. Weakness was the most prominent subjective complaint and was present in twenty-eight of fifty-seven cases investigated. Backache, headache and cardiac symptoms were likewise complained of. Thirteen women developed gallbladder disease. The authors conclude that the liver suffers more damage in eclampsia than do the kidneys.

Glycine Treatment of Progressive Muscular Dystrophy—Kostakow and Slauck report their observations on the effects of oral administration of glycine in seven patients with muscular dystrophy and in four persons without this

disorder In the seven patients with muscular dystrophy they noted that the creatinuria was increased by several times its initial value Parallel with this went a decrease in the absolute elimination of the preformed creatinine After approximately four weeks the creatine elimination again reached its initial value and the metabolism approached normality It seems that the phosphagen content of the muscles can be influenced with this amino acid Whether, besides influencing creatine formation glycine exerts yet other influences remains as yet undecided On the basis of their metabolic studies, the authors conclude that muscular dystrophy results from the loss of the capacity to utilize creatine Under the influence of glycine, the organism regains this capacity and the metabolism becomes normal

Cardiac Thrombi—Besser and Schilling discuss the clinical aspects of thrombi of the heart on the basis of cases reported in the literature and of cases of their own observation They show that the clinical manifestations depend on whether the thrombus is located in the right or in the left heart, whether it is a free thrombus, and whether it is pedicled or mural Cardiac thrombi are, as a rule, more frequent in the auricles than in the ventricles The authors discuss the roentgenologic visualization of the thrombi of the heart and the diseases of the neighboring organs which are important in the differential diagnosis They emphasize particularly that now cardiac thrombi will be more often recognized than was formerly the case, and that this is primarily owing to roentgenoscopy eventually with the aid of kymography However, it is necessary that the clinician and the roentgenologist cooperate, for in many instances the roentgenologic verification of the diagnosis is not possible without an exact knowledge of the clinical data

Diabetes Insipidus and Mellitus—Lindeboom relates the clinical history of a woman who had suffered from diabetes insipidus for several years and then developed diabetes mellitus The author discusses several problems connected with this rare combination He admits that, in the reported case, responsibility for the diabetes may be imputed to hypophyseal influences, which by way of the nervous regulation of sugar metabolism from the base of the third ventricle exerted an influence on the liver But in view of the insular aspect of the disturbance of the sugar metabolism this does not seem so probable The author is inclined to regard the condition as a pluriglandular disturbance of syphilitic origin although a connection between the different functional disturbances is not perceptible However, he considers the regular menstruation at the age of 55 additional evidence for an anomaly in the internal secretions of the patient He shows that salyrgan has a diuretic effect in diabetes insipidus and that it is also capable of increasing the sodium chloride concentration of the urine to values that are extraordinarily high for diabetes insipidus

Roentgen Irradiation in Tuberculous Meningitis—Wiener was induced to employ roentgen therapy in tuberculous meningitis by von Bokay's report, stating that five of seventeen patients with tuberculous meningitis had recovered as the result of roentgen irradiation He followed the suggestions of von Bokay and administered comparatively high doses The description of the nine cases in which the author employed roentgen treatment reveals that irradiation was never effective Moreover, he does not even consider the method free from danger, because he always noted an exacerbation of the process after the first irradiation and he had the impression that death had been hastened by this treatment In trying to explain the discrepancy between his own unfavorable results and the results obtained by von Bokay, he points out that von Bokay's cases

were all comparatively new, while his were somewhat advanced Nevertheless, he has now completely abandoned the roentgen treatment of tuberculous meningitis

Therapeutic Use of Weed's Experiment in Meningitis—Mikulowski relates the clinical history of a boy, aged 11 noteworthy because the patient had had chronic cerebrospinal meningitis for more than a year and had not been given any medical treatment Five acute attacks had been treated with home remedies and palliatives During the sixth attack which was unusually severe the boy was hospitalized The case is interesting from the clinical point of view because it shows the difficulty of diagnosing chronic cerebrospinal meningitis for there was no increased temperature, the intervals between the different attacks were comparatively long and the first examination of the cerebrospinal fluid was negative However the author emphasizes that this case demonstrated the diagnostic significance of Flatau's chromoneuroscopic reaction After reviewing several other cases in which cerebrospinal meningitis was characterized by successive attacks, and after evaluating the causes of this peculiarity the author discusses Weed's experiment of increased cerebrospinal pressure following the injection of distilled water Because the patient showed signs of hydrocephalus and because the discharge from the cerebral ventricles was impeded and resulted in stasis, the author resorted to intramuscular injection of distilled water, and as a result the signs of blockage disappeared The injection produced an increase of pressure in the cerebrospinal canal, and it not only facilitated the discharge of the fluid and the introduction of the therapeutic serum but also the equalization of the intracranial and intramedullary pressure.

Blood Picture of Pernicious Anemia in Stenosis of Small Intestine—Schlesinger reports the clinical history of a woman, aged 54, with stenosis of the small intestine and with the symptoms of pernicious anemia The gastric juice which had a normal acidity, was tested for the presence of the antianemic principle It was found that in contradistinction to the case with multiple stenosis of the small intestine described by Castle, the antianemic principle was present in this woman The author concludes from this observation that the hyperchromic megalocytic anemia, developed on the basis of the stenosis of the small intestine, was not produced by the action of the intestinal stenosis on the gastric function or by the absence of the deficient resorption of the antianemic factor, and that therefore the presence of an anemia of the pernicious type is not dependent on the absence of the antianemic principle

Plasma Coagulation Phenomenon of Staphylococci—Gross calls attention to the fact that in operations during staphylococcal diseases, such as in surgical interventions on carbuncles or on osteomyelitis, blood coagulation is frequently accelerated This observation was reported as far back as 1908 by Much, who showed that this coagulating power is most pronounced in *Staphylococcus aureus* *Staphylococcus albus* likewise contains the coagulating factor but to a lesser degree than *S aureus* After describing the method employed in the tests in vitro, the author mentions other investigators who found that only the pyogenic staphylococci have the coagulating capacity, and that for this reason the coagulation test can be employed in the differentiation between pathogenic

and apathogenic staphylococci. He himself was able to corroborate that the coagulation of citrated blood is a characteristic of living staphylococci and also that, to a certain extent this test permits a classification of pathogenic and apathogenic staphylococci. Other experiments revealed that not only *S. aureus* as such but also its filtrates contain the coagulating substance. He describes tests on rabbits proving that intravenous injection of small amounts of the coagulating substance resulted in intravascular coagulation and in the formation of thrombi. From this observation he concludes that the coagulating substance of staphylococci may be of etiologic significance in certain forms of thrombosis in human subjects. Finally, he discusses the existence of an antibody which inhibits the coagulatory action. In collaboration with Mondry, he found that coagulability is decreased in serums with a high antitoxin content.

Antigen Specificity of Serum Euglobulins—Lehmann-Facius describes experiments which indicate that, in malignant tumors and in tuberculosis, the euglobulin fraction of the blood serum (hydrochloric acid globulin) has a certain agglutinating action, and that by means of a special method it is possible to demonstrate an antigen specific character in the euglobulin fraction of the majority of cancer and tuberculosis serums. A new serodiagnosis of these diseases is thus made possible by so called cross experiments with certain test serums and entirely without the use of artificial extracts. Because of the cross arrangement it is possible to examine every serum simultaneously in two directions for its antibody content by means of test antigen serums and for its antigen content by means of serums with known antibody content. The method is based on the centrifugation of mixtures consisting of cooked and native (with lecithin preabsorbed) euglobulins in the course of which the sediments, following shaking with solution of formaldehyde may give conglobation reactions, provided homologous serums (carcinoma serums on carcinoma serums and tuberculosis serums on tuberculosis serums) have acted on each other in the combinations. In this manner it is possible to demonstrate even saturated antigenic substances in the serum independent of the quantitative combination ratios. The simultaneous examination of the same serum with the antigen reaction as well as with the antibody reaction provides a greater range for the reaction, since some of the serums react only toward one side. It has been impossible so far to differentiate definitely between sarcomas and malignant tumors of different histologic structure, in spite of the fact that the different tumor serums may show a varying capacity of reaction toward the respective serums. The simplification of the square cross method suggested by the author is to use mixed coetoglobulins or mixed antiglobulins as reagents of greater "dispersion." He considers the factors of "disintegrating immunity" the foundation for the development of the described antigens.

Incretory Action of Salivary Glands—Following a discussion of the literature, Glaser and Bannet describe their own investigations. They reach the conclusion that the salivary glands have no internal secretion of the nature of an insulin-like body or of secretin. However, they were able to demonstrate that the external secretion of the salivary glands in addition to other ferments, also contains peroxidase and oxidase, and they think that this external secretion by nature of its composition, is capable of compensating at least partly for the lack of pancreatic secretion. The enlargement of the salivary glands, observed by clinicians in patients with diabetes mellitus, would thus find its logical explanation. The practical conclusion the authors draw from this is that the external secre-

tion of the pancreas should not be neglected in the treatment of diabetes mellitus but that its deficiency should be compensated for by substitutional preparations.

Vascular Disturbances with Attacks of Pain—Schretzenmayr shows that the mechanical conditions for the development of an arterial dilatation exist in the chronic vascular disturbances, such as ambulatory angina pectoris abdominal angina and intermittent claudication, in which the attacks of pain concur with an increase of the blood pressure. However, in vascular embolism in which the pain is much more severe and an increase in blood pressure is absent, there is no dilatation of the arteries, nor can it be expected on the basis of the physical factors. Thus, the pain of those chronic vascular disturbances seems to favor the ischemic theory, that the dilatation of the arterial wall is only a facultative symptom, dependent on the facultative increase in the general blood pressure. Consequently the dilatation cannot determine the nature of the pain. The solution of this problem is of great significance for the treatment of these attacks of pain. If the treatment is based on the dilatation theory it would be necessary to keep the blood pressure as low as possible. On the basis of the ischemic theory however, a treatment with this aim in view would certainly be wrong in many cases such as in angina pectoris. It has been found that the blood perfusion of the coronary system, like that of other vascular systems, is largely dependent on the arterial pressure. A decrease in blood pressure without simultaneous dilatation would cause a decrease in the blood perfusion, that is, the ischemia would become exacerbated. The ischemia theory indicates that the medicaments of the epinephrine group, which increase the blood pressure without contracting the coronary vessels, are the most effective in angina pectoris and this has been proved in many cases which although they did not react to epinephrine, were influenced by ephedrine. But, in employing these remedies one should not overlook that by increasing the arterial pressure the impaired heart is taxed quite strongly. Attempts to decrease the pressure in patients with high blood pressure are in accordance with the ischemic theory in that, by relieving the heart from overburdening, the relation between blood requirement and blood supply becomes more favorable. In addition to the old and tried nitrite preparations, various circulatory hormones have been tried to obtain vascular dilatation but in most instances without the desired results. The authors emphasize that as a rule only the component of ischemia resulting from a functional change in the tonus of the vessels can be influenced and, for this reason even the best treatment will be effective in only some of the patients.

Achylic Blood and Nervous Diseases—Under the heading of achylic blood and nervous diseases, Sinek discusses pernicious anemia achylic chloranemia and funicular myelitis. He gives as the reason for considering together these essentially different conditions the fact that it is quite often difficult to differentiate them, and also that achylia gastrica and the bacterial conditions in the small intestine related to it occur in the three conditions. After discussing the symptomatology of pernicious anemia, he evaluates the various therapeutic methods, such as the treatment with raw liver, liver extracts, a preparation of hog stomach and injectable liver extract. He considers iron therapy valueless in pernicious anemia but points out that arsenic therapy is often helpful. Blood transfusion, advisable particularly in cases in which the hemoglobin content is extremely low and during the time before the liver extract becomes active, not only is

a substitution therapy but also has a stimulating effect on the bone marrow. In discussing achylic chloranemia the author describes particularly certain differential diagnostic symptoms, such as the hollow shape, thinness and brittleness of the nails and the difference in the color of the skin and in the blood picture, as compared with what is found in pernicious anemia. Medication with iron is the most effective form of treatment, whereas arsenic and liver prove ineffective in this form of anemia. The good results occasionally obtained with liver therapy are probably the result of the high iron content of the liver. In the discussion of funicular myelitis, the author points out that this condition may develop as a complication not only of pernicious anemia and of chloranemia but also of beriberi, pellagra, sprue, scurvy and syphilis. The most important symptoms are paresthesias, disturbances in the deep sensibility and motor disturbances. He shows how funicular myelitis can be differentiated from tabes and from Friedreich's ataxia. In the milder forms he frequently found liver treatment helpful, but in the severer cases this treatment often failed.

Polycythemia and Symptoms of Menière's Disease—Koch and Rothmann call attention to the fact that a diet with high fat content but with a restricted quantity of salt and meat has been successfully employed in the treatment of polycythemia. They relate the case of a man of 37 in whom the symptoms of polycythemia (over six million erythrocytes) and increased hemoglobin content (140 per cent) concurred with manifestations resembling those of Ménière's disease, such as attacks of vertigo, vomiting and tinnitus. The otologic examination seemed to show that the symptoms indicative of Ménière's disease must have been caused by lesions of the central nervous system. Since polycythemia is accompanied by an increase in the quantity of blood and by abnormal blood perfusion, such as stasis, hyperemia or retardation of the blood stream, it is probable that diapedesis took place in the central nervous system. The likelihood of this cause is borne out by the fact that symptoms resembling those of Ménière's syndrome are observed also in patients with arteriosclerosis and as an early sign of cerebral sclerosis without signs of involvement of the internal ear. Aside from these considerations, which seem to prove a relation between the polycythemia and the Ménière syndrome, the authors point out that in the reported case the fat diet had a favorable influence on the polycythemia and improved the symptoms indicative of Ménière's disease.

Treatment of Chondral Arthritis Deformans by Cartilage Extract—Eisenklam employed a cartilage extract in the treatment of thirty-six presenile or senile patients with chondral arthritis deformans. The extract was prepared from the cartilaginous portions of the bones of calves. After the cartilage was chopped fine it was mixed with physiologic solution of sodium chloride and this mixture was kept for twelve hours at room temperature. Then it was extracted, filtered and dialyzed. The dialysate was concentrated in the vacuum and under low temperature, filtered, sterilized by heat and put in ampules. Thus a protein-free solution was obtained that contains all dialyzable constituents of the cartilage. The extract was administered by subcutaneous injection. First, 1 cc. was given daily for four days, then 2 cc. daily for four days and after that 3 cc. daily for from seven to fourteen days. Following this, the dosage was decreased, so that during the fourth week 1 cc. was administered daily. A considerable improvement was effected within from four weeks to three months in twenty-four of the patients. The pain was lessened and the movements were improved. In the patients in whom the cartilage extract alone did not bring the desired results, a new series of injections was given and was combined with roentgen irradiation. This combination therapy proved effective in several cases.

Bronchial Asthma as Hysterical Psychosis—According to Edel, bronchial asthma is readily recognized during the attack but the diagnosis is difficult during the attack-free period, particularly when emphysema has not yet developed. More or less severe bronchitis may be a result of the disease but is not necessarily pathognomonic. When there are no positive signs the physician may be inclined to rely on the statements of the patient, without paying sufficient attention to the clinical aspects. The patient may even come for con-

sultation with his own diagnosis, and treatment may be instituted on the strength of this. The author observed two cases of hysterical simulation of asthma, which are of especial interest because of the rare etiologic factors, the course of the disorder and the attendant circumstances. He succeeded in overcoming the psychic conflicts by the use of patience and kindly interest. Repeated consultation assiduous explanation of even the minor problems of the patient, and the employment of mild sedatives led the patient back to a more normal life.

- Treatment of Colics of Urinary Passages W. Grossmann—p 345

Tuberculosis and Light Baths—Jesionek points out that light baths have a curative effect not only on tuberculous foci in the skin but also on tuberculous processes within the body. On the other hand, it is possible that light baths produce an unfavorable influence on tuberculous processes. The author bases the explanation of the mechanism of this function of the skin on experimental studies indicating that the skin has an antituberculous function and is the source of the natural defense substances of the organism against the tubercle bacillus. He considers these substances as esophylaxins and designates them as epidermidal antituberculins. Already Robert Koch had noticed that the intracutaneous introduction of killed tubercle bacilli gives a quite different reaction from that caused by the subcutaneous administration. Following a discussion of animal experiments and of observations on human beings the author points out that in civilized human beings the epidermal source of the natural and antituberculous defense substances flows slowly and deficiently because only a small portion of the skin is exposed to the adequate stimuli provided by air and light. The light and air bath withdraws the skin from this unnatural condition, interrupts the evenness of the light and temperature status to which the skin of civilized human beings has become accustomed, and frees the skin from the confining influences that reduce its metabolic functions. The first stimulus exerted by the light and air bath following the removal of clothing depends on the fluctuations in the temperature. The reduced temperature, the increased pressure exercised by movements of the air and the influence of the light increase the blood perfusion of the skin and this combination of stimuli by way of the parenchyma cells that are susceptible to stimuli of heat, pressure or light, regulates the blood perfusion and the blood content of the skin. In this regulation of the blood supply of the skin the author sees the most important biologic action of the light and air bath, because the blood supply determines the nutrition, the chemical composition, the warmth and the pressure of the skin as well as the function and the metabolic rate of the skin cells. The increase in the blood perfusion also enables the skin cells to produce antituberculous and tuberculo-lytic substances. In order to avoid the possible detrimental effect of the light and air bath in tuberculosis it is essential not only to avoid light induced inflammation of the skin but also undercooling and overheating for such influences may paralyze instead of stimulating the parenchymal cells of the skin.

Ultraviolet Rays and Catalase Content—Koeppel calls attention to the fact that the great significance of catalase for all oxidation processes in the organism and its consequent importance for all life processes of the cells is based only on the factor that all cells decompose hydrogen dioxide and that therefore all cells must contain catalase. In certain times the catalase has been measured by determining the oxygen liberated in the decomposition of hydrogen dioxide. Certain aspects of this energy determination could be studied through the influence

exerted by the ultraviolet rays of the quartz lamp on hydrogen dioxide, and the experiences gained thereby were an advantage in catalase determinations of the blood. The author discusses a number of investigations on the action of the ultraviolet rays on ferments and shows that many of them contradict one another. His own studies likewise contradicted one another at first for the influence of irradiation on the blood catalase became manifest either as an increase or as a decrease in the catalase value. Only after the initial value had been given consideration did these results become clearer. It was found that, when the initial catalase values were high irradiation with ultraviolet rays effected a decrease, whereas a low initial value was found to be increased after irradiation. Thus the catalase content plays an important part in the determination of the correct dosage in ultraviolet ray treatment of rickets. The author's studies convinced him that children with low or average catalase content are suitable for ultraviolet ray treatment while those with high catalase content are not. In children in whom ultraviolet irradiation was omitted because of high catalase content, improvement set in just the same. The author admits that catalase determinations before and after irradiation with ultraviolet rays reveal only the response of the organism to irradiation, but he admits that this test method cannot replace the "erythema dose test, for there are no relations between the two test methods.

Treatment of Functional Amenorrhea. R. Hofstätter—p 275

Injection Treatment of Hemorrhoids—Henninger reviews the history of the injection treatment of hemorrhoids and describes his own observations on sixty-seven patients. At first he used 70 per cent alcohol and, in the case of internal hemorrhoids he always obtained good results with this method, but the injection into a subcutaneous nodule resulted in gangrene. This induced him to try a milder substance and on the basis of Winkler's report, he tried the various types of sugar in glycerin, which he had found helpful in the treatment of more than 100 cases of varicose veins. He tried dextrose, lactose and galactose with glycerin, and he is as yet unable to say which of these is the most effective. The solutions employed by him were a 10 per cent solution of dextrose in undiluted bidistilled glycerin, either alone or with the addition of 4 per cent quinine hydrobromide, a solution of from 20 to 25 per cent galactose in bidistilled glycerin and a 10 per cent solution of quinine hydrobromide in 70 per cent alcohol. The author points out that the unfavorable results reported from the injection treatment probably concern the external hemorrhoids, because the skin reacts differently from the mucous membrane. For this reason he advises the employment of different injection fluids for the external and internal nodules. For the internal nodules he recommends the use of alcohol or of alcohol with quinine, and for the external nodules he employs only the sugar glycerin combinations. The doses should be small if alcohol is used, from 0.5 to 1 cc. should be injected in each nodule, and in case of the sugar glycerin combinations from 1 to 1.5 cc. should be given. These combinations should be warmed before injection to make them more fluid. It is generally possible to treat all existing nodules in one session.

Parenteral Treatment of Pernicious Anemia—Schechter shows that the parenteral treatment represents considerable progress in the therapy of pernicious anemia. It is particularly helpful in advanced cases and makes it possible to treat them effectively without blood transfusion. The author made his observations on the injection therapy in seventeen cases nearly all of which were quite severe. He obtained good results with injectable liver extracts and also with intramuscular injections of biogenic amines particularly with choline. In cases that were refractory to oral liver therapy, a combination or alterna-

tion of injections of liver extract and of choline proved helpful in that the blood status became normal or even supernormal. There was no absolute failure, nor any fatality among the seven cases in which the author employed the injection therapy.

Blood Transfusion—Smirnov and Ermolenko report their observations in 260 blood transfusions performed on 189 patients. When the main indication was to increase blood coagulability, they resorted to the citrate method. Citrated blood with dextrose was used when the indication was to replenish the blood-vascular tree. After copious hemorrhage, whole blood was given. They insist on the use of the three drop method of Nuerenberger for the compatibility test in every case in addition to grouping of the donor and the recipient. In three of their patients the test was positive in otherwise corresponding groups. They believe in the use of relatively small doses, from 100 to 200 cc., to accomplish hemostasis. They conclude that blood transfusion is the most potent means of combating a hemorrhage. The effect is beneficial but evanescent in acute septic conditions, the percentage of permanent improvement being insignificant. In chronic sepsis, blood transfusion gave a high number of permanent recoveries especially when combined with specific vaccine therapy.

Blood Picture in Endocarditis—Vydrin reports on hematologic studies in twenty-five cases of endocarditis. Of these twenty patients had chronic endocarditis and five had the acute form. In four of the patients with chronic endocarditis he found in addition, a glomerular nephritis. Shilling's method of counting was used. The blood picture in the acute endocarditis showed an erythrocyte count of 2,000,000 or lower a hemoglobin percentage of from 20 to 35, a neutrophil leukocytosis with deviation to the left (Schilling), and a presence of juvenile forms of from 5 to 8 per cent. Such a picture offered a poor prognosis. Three of the five acute cases proved fatal. The red count in the milder cases was from three and one-half to four million and the hemoglobin from 60 to 70 per cent. The color index vacillated between 0.6 and 0.7. There were signs of secondary anemia both in the acute and in the chronic cases in which septic manifestations and poor resistance were present. In two patients the blood picture approximated that of pernicious anemia, the erythrocytes fell to 1,030,000 and the color index was 0.9 per cent. A leukocyte count of from 10,000 to 12,000 was found in eleven patients, and in cases complicated with glomerulonephritis the count reached 18,000. The differential count showed from 84 to 86 per cent of neutrophils with a deviation to the left from 2 to 4 per cent of juvenile forms and a lymphopenia. In favorable cases, leukocytosis disappears and the lymphocytes increase. Six patients with septic manifestations and poor resistance presented a picture of leukopenia. Monocytosis of from 12 to 16 per cent was seen in patients with good resistance and a favorable course. The blood picture in the three fatal cases showed a sharp deviation to the left on the part of the neutrophils, with a juvenile cell count up to 11 per cent and a 20 per cent monopenia. Eosinophils were present in twenty-two cases but did not appear to have any diagnostic significance. A lymphocytosis of from 35 to 40 per cent without a deviation to the left was present in six cases. These were cases with a favorable course. Changes in the vascular-endothelial system mentioned in the literature and manifested by the presence of endothelial cells in the circulating blood were observed in only two cases and in these the chronic endocarditis was complicated by a syphilitic aortitis. The author did not observe any improvement from blood transfusion.

TRAUMATIC ULCER OF THE DUODENUM AND STOMACH

BURRILL B CROHN, M.D.

NEW YORK

AND

JULIUS GERENDASY, M.D.

ELIZABETH, N. J.

A case of duodenal ulcer following on, and probably caused by, abdominal trauma was recently called to our attention. This case, with all the details and roentgenographic observations, has been described by one of us¹. In studying the etiologic traumatic factors which we believed led to the formation of the ulcer, we had occasion to look into the literature, not only of our own country but of foreign countries as well. Having established to our own satisfaction that in at least this one instance the relationship of the trauma to the duodenal ulcer was one of cause and effect, we were surprised to learn two supplemental facts: first, that American literature fails to take serious notice of the possibility of such an occurrence or glosses over the fact, many if not most American clinicians probably denying the existence of such a relationship; second, that foreign publications not only recognize the fact that traumatic ulcer of the duodenum or stomach does occur, but German and French literature is replete with very illustrative examples and references and not only recognizes its existence but describes in detail the *modus operandi* of the trauma, the clinical manifestations that accompany the formation of the lesion, and the clinical course of this unusual ulcer syndrome.

Approaching the subject at first with a healthy skepticism, we soon recognized the validity of the foreign writers who described this clinical picture. By the same token we had occasion to find fault with the undue diffidence and skepticism of our own students of gastro-enterology in refusing to accept the concept of traumatic gastric ulcer. What was even more noteworthy was the fact that most of our own confreres who should have been in a position to pass an opinion were usually entirely ignorant of the existence of the problem, if a problem existed, or had no personal knowledge of, or experience with, the underlying facts or premises of the thesis.

A brief review of the facts in the case which so impressed itself on us is as follows:

A woman, aged 45, who never had any previous digestive disturbances or complaints, was violently thrown out of a seat of a bus, late one afternoon and catapulted across the aisle so that the epigastric area of the abdomen forcibly struck a projecting edge of the opposite bench. She complained forcibly

of the pain but was able to proceed to her home. The next morning she felt a less severe epigastric distress, on evacuation of the bowel she noted that the stools were 'black' (melena). Two days later she felt nauseated and vomited a large quantity of blood. She was removed to a hospital where the hematemesis was repeated several times, associated with melena. The physical examination at this time, aside from the shock, revealed a large bruise to the right of the epigastrium. She left the hospital about a month after admission, the gastric hemorrhage being controlled by the usual conservative methods.

The course of the case has been characteristic of a typical Moynihan duodenal ulceration. There were periods of symptoms of severe pain, heartburn, vomiting and relief by food and alkalis, alternating with other periods of relative quiescence. Two further roentgenographic studies, one taken one month after the accident and a third series taken thirteen months after the injury, all clearly corroborated the presence of a duodenal ulcer characterized by deformity of the duodenal bulb, pylorospasm and a slight six-hour gastric residue. Two years after the injury, and in spite of repeated courses of medical treatment (bed rest, alkalis, the Sippy diet) one has no difficulty in recognizing all the features of a true duodenal ulceration characterized clinically by postprandial pain, vomiting, heartburn and loss of weight. Epigastric tenderness on deep abdominal pressure persisted. The question of operative intervention, two years after the occurrence of the trauma and of the onset of symptoms, has been broached on account of the persistence and the severity of the symptoms.

Approaching the subject in a dispassionate and purely juridical mood, one must recognize that before, and up to the moment of the accident there were registered absolutely no digestive disorders or other abdominal or general complaints. Directly following the injury, or within twenty-four hours, we noted the development of symptoms, of signs and within two weeks, of the roentgen deformity of a duodenal ulcer. The evidence seems convincing that the trauma caused the ulcer. Before drawing such a final conclusion, one must consider and dismiss such contrary arguments as may be advanced.

Could a silent ulcer have existed prior to the accident? Is the patient a malingerer, or at least exaggerating and creating symptoms so as to establish a legal claim for compensation or for an award in a suit in negligence?

It is true that about 5 per cent of the adult population have, or have had, a gastroduodenal ulceration. It is probably equally true that in some of these individuals ulcer may be passive, dormant or latent. In this individual there was no previous history of ulcer of the digestive tract and nothing to point to its existence. Furthermore, this patient is normally sensitive and even hypersensitive to pain by the styloid pressure test of Libman,² and for this reason, and on the basis of our experience with pain sensitivity in ulcer, we do not consider it likely or probable that an ulcer could have existed without consciousness of its existence.

² Libman E. *Tr. A. Am. Physicians* 41: 305, 1926; 44: 52, 1929.
Crohn B. B. *Am. J. Surg.* 7: 474 (Oct.) 1929. Libman Anniversary
Volume. International Press 1: 337, 1932.

¹ Gerendasy Julius. *Am. J. Surg.* to be published.

We are, to be sure, lacking a radiographic study of the stomach before the accident, but such evidence would be possible only by a rare coincidence.

Against the argument of malingering or exaggeration on the part of the litigant, it must always be remembered that an ulcer deformity and niche was three times shown to exist in the duodenal cap. It is the actual existence of this ulcer deformity that interests us scientifically, not the degree of complaint that is at issue before us.

MEDICAL LITERATURE

From a perusal of the American literature and textbooks it soon becomes evident that the passing references and guarded opinions which refer to this subject are based on the experiences of other, usually foreign, writers. There are no publications in American medical journals that deal clearly with this subject or which exhibit first-hand information, experience or case histories.

The fact that foreign literature and many foreign writers accept the premises and the conclusion make it all the more important that the subject be thrown wide open for critical discussion by the resident members of our own profession, known in this country for their critical reserve and healthy skepticism toward new concepts and suggestions.

A comprehensive review of the foreign literature on this subject is contained in the 1930 edition of Richard Stern's textbook.³ Traumatic surgeons recognize the fact that severe abdominal blows may lacerate a stomach. Such blows dealt directly, as a kick or a heavy body falling on the abdomen, automobile injuries and falls from a height, constitute the principal means by which such traumas are administered. Under such conditions, such a severe blow will cause injuries of the gastric wall, varying from mucosal and submucosal lacerations with extravasation of blood (submucosal suffusions) or acute hemorrhages with separation of the mucosa for varying extents. Greater blows may cause actual ruptures of all or of several of the coats of the stomach wall. Such injuries usually occur on the lesser curvature of the stomach, at or near the pylorus, or may rupture the fundus completely by sudden elevation of the intragastric pressure to the bursting point.⁴ The milder types of injury may regress with healing, death may ensue from hemorrhage or perforation, immediate surgical intervention may save the case, or, probably, an ulcer of the mucosa and the walls may follow as a sequel.

There are certain oft-quoted animal experiments that most writers are fain to refer to because of their reputed value in establishing such injuries. The two authors most quoted are Vanni⁵ and Ritter.⁶ Both writers used rather crude methods to establish their point. In all experiments a dog was anesthetized and tied, abdomen upward, on a table, a violent blow was dealt the abdomen with a heavy stick or hammer. There was no difficulty in producing lacerations and rupture of the stomach under these experimental conditions, particularly when the experiment was carried out directly after a full meal had been given. One can

see little point in these experiments, for true ulcers have never been seen in the dogs, even when they were allowed to survive for varying periods. In most of the animals in which the injury was sublethal, evidences of healing were readily demonstrable, this fact agrees with the experience of most laboratory workers who have attempted to produce ulcers in animals by creating mucosal defects, by mucosal injection experiments, or by other means. All such defects heal readily if the conditions of the experiment remain uncomplicated.

CLINICAL OBSERVATIONS

In 1856, Potain⁷ first described a case in which he attributed to a blow on the abdomen the formation of a gastric ulcer. This is the classic case which initiates the literature on the subject. A falling piece of furniture struck a woman aged 60, on the abdomen. A continuous course of eight years of clinical symptoms of ulcer followed, death by inanition eventually resulting. At the autopsy a traumatic hour-glass stomach was demonstrated, with an ulcer 2 by 5 cm placed "à cheval" on the lesser curvature and penetrating the body of the pancreas. The case was presented in the clinic of Cruveilhier, the latter himself presiding, with no less a pathologist than Axenfeld to demonstrate the morbid specimens. All those present agreed to the correctness of the facts and to the conclusion that the ulcer was traumatic in origin. The historical background and interest in this demonstration were notable.

The case of Potain marks the beginning of the interest in this subject. At varying intervals, successive cases were reported, so that by 1913 Petit⁸ was able to recount no less than seventy-three plausible cases. Of course, the objection may well be raised that between 1856 and 1903 most of the citations were purely clinical observations, unsupported by autopsies or biopsies, occurring before the utilization of x-rays for verification, and before the recognition of the existence of duodenal ulcers (Moynihan, 1903). Such objections are scientifically logical and call, therefore, for a more critical scrutiny of all the clinical data and for a rearrangement and readjustment of the facts.

CASES RUNNING A SHORT COURSE WITH RECOVERY

Dumény,⁹ in 1903, was able to collect eighteen such likely cases, since which date many other examples have been added. The injuries are of varying natures but are generally catalogued as (1) blows by falling bodies, usually heavy articles of furniture, falling wagons or massive crates, (2) injuries caused by a punch, a kick, human or animal, among which kicks by horses are the most common, (3) falls from heights, landing on the abdomen and striking projecting surfaces, (4) being run over by a wagon or an automobile, or compression injuries resulting from railroad accidents. The injuries in all instances were severe, lighter blows or falls rarely being recorded as leading to this symptom complex. Within a few hours, or from one to six days following the injury, pain, vomiting and distress supervened. The vomiting of blood may occur almost immediately or, at times, from twelve to twenty-four hours, later, or may occasionally be postponed for from one to two weeks. After the initial shock (or collapse as the case may be), the full picture of a gastric injury becomes evident, quickly assuming the char-

acteristics of an ulcer, gastric or duodenal. The course is run in from a few weeks to six months, almost always resulting in a clinical cure. The cases that become chronic and exceed this time limit (six months) or develop complications are discussed later.

ACUTE TRAUMATIC PEPTIC ULCER, SHORT COURSE

The following typical examples of this type of case with spontaneous resolution are cited from the voluminous literature.

A man, aged 38, was kicked in the right hypochondrium by the hoof of a horse. Immediate vomiting and violent cramps set in. The next day there was repeated hematemesis with melena and severe postprandial pain. There was rapid loss of weight and marked epigastric tenderness on pressure, and diarrhea. Under treatment with bed rest and milk diet for three weeks, all symptoms regressed.¹⁰

A man, aged 57, was struck by the shaft of a wagon in the upper part of the abdomen. Immediate violent pain set in at the site of the injury. Eight days later vomiting began, which recurred daily in spite of strict dietary treatment. There was marked epigastric tenderness on pressure. Resolution occurred after six weeks.¹¹

These two classic cases are quoted merely as examples of instances of traumatic ulcer which, after a short course, responded favorably to treatment and recovered. In the earlier reports from the literature actual proof or visual demonstration of the existence of the ulcer is lacking. Roentgenographic or operative confirmation does not exist, and yet the sequential rise of the ulcer from the injury seems plausible. But there are occasional cases cited in later literature in which without any history of a previous gastric disease, an ulcer was visually demonstrated as resulting from an injury. The following cases may be cited as illustrative examples.

A railroad employee was caught between two cars, pain and loss of appetite resulted. Six months later, severe attacks of abdominal pain became pronounced. A progressive downward course followed. At autopsy a perforated gastric ulcer was observed on the lesser curvature, 1.2 cm from the pylorus. In this case, the length of the time between the injury and the onset of severe symptoms somewhat weakens the argument favoring a traumatic origin of the ulcer.¹²

A man was kicked with great violence in the upper part of the abdomen by the hoof of a horse. Five days later, fatal hemorrhage supervened. At the autopsy three ulcers were seen, situated on the lesser curvature of the stomach, one of which enclosed a large perforation.¹³

As a striking instance of the rapidity with which characteristic duodenal ulcers may form, we may cite the following case.

A man aged 39, was violently struck by a heavy falling body, and died sixty hours later of injuries to the thoracic organs. A fresh bleeding, acute duodenal ulcer was exposed at autopsy, open vessels lying free in the necrotic walls and base of the lesion. This case is of unusual moment as demonstrating the rapidity of the formation of peptic ulcers, a fact that has been clinically conceded by experimental pathologists for the usual peptic ulcer and must now also be conceded for traumatic lesions.¹⁴

While such instances are striking in their evidence, it is obvious that unsupported by further facts the case for a traumatic origin of an indurated gastric or duodenal ulcer of the Cruveilhier type is still incomplete. One must therefore rely for further evidence

on the type of case in which a typical chronic peptic ulcer followed abdominal injury. The literature is replete with such citations, probably not less than fifty or sixty examples being susceptible of notation. Most of the cases followed long periodic courses, the clinical symptoms being characteristic of a peptic gastric or duodenal ulcer. Actual proof of the ulcer, however, is lacking. There are a few cases in which operation or autopsy bring full confirmation of the existence of the ulcer and make the traumatic etiologic factor so plausible as to be almost undeniable.

CASES ILLUSTRATING THE CHRONIC TYPE OF ULCER

The following are examples of the chronic type of traumatic ulcer.

A man, aged 40 a ranger, was traumatized by a fall against the butt of his own rifle. For several hours he had severe abdominal pain but no vomiting, later pains recurred regularly after meals. Relief followed after eight days but two months later pain, and now vomiting recurred with greater intensity. Severe heartburn belching and pain followed within a few minutes of the completion of the meal with vomiting from five to six hours later. Several weeks later, severe hematemesis resulted in syncope, followed by progressive emaciation induced by protracted pain and vomiting. The man was pale, anemic and emaciated and showed marked epigastric tenderness on pressure. Gastric lavage and dietary treatment were actively instituted, with progressive relief. The patient was observed on and off, for three years when eventually the symptoms ceased.¹⁵

A man, aged 31, was involved in a railroad accident, being compressed simultaneously in the epigastrium and the back. Fifteen days later he began to complain of postdigestive distress with vomiting half an hour after each meal. Two months later, during the progress of the case, he was suddenly seized with severe hematemesis, he showed severe epigastric tenderness on examination. For six months there was a progressive downward course, in spite of very intelligent medical treatment. One year later the patient was still vomiting, often with blood. After a protracted course of two and one-half years, spontaneous healing occurred, with full recovery.¹⁶

Innumerable other cases of this type might be cited, Stern³ giving several very plausible examples of traumatic ulcer. However, the actual visible proof being absent, this group of cases is left in the category of likely and probable, rather than proved, instances.

CASES OF CHRONIC TRAUMATIC ULCER PROVED BY OPERATION OR AUTOPSY

A third group, however, offers real proof of the existence of an ulcer following directly, or soon after an accident to the abdomen, in which, previous to the trauma, no evidence or suspicion of a gastric lesion had existed. Of this group, the following represent some but not all of the outstanding examples.

A patient had been injured by a violent blow on the abdomen. Vertigo and shock resulted, with rapid successive hematemesis. After one month, some improvement in the general condition was noted, but the postdigestive complaints were maintained, though the hemorrhages had ceased. About three months after the accident a definite diagnosis of post-traumatic ulcer was made on account of the severe postprandial pain vomiting and progressive emaciation. Two years after the accident the patient died of pulmonary tuberculosis, at the autopsy a cicatrized plaque was observed on the lesser curvature of the stomach, midway between the pylorus and the cardia, from this cicatrized area scars radiated for 6 cm in several directions.¹⁶

Potain's case, which was referred to earlier in this article,⁷ represents a bona fide instance of an ulcer demonstrated at autopsy to have followed on and existed for eight years after the accident. The position, size, and cicatrization of the ulcer on the lesser curvature demonstrates strong evidence, since the site corresponded to the location of the injury, and the symptoms followed directly on the trauma.

A woman, aged 67, sustained a violent fall on the abdomen, subsequent to which she complained consistently of post-digestive pain. Two years later she had a sudden, enormous and fatal hematemesis. At autopsy the stomach contained liquid blood and was the seat of a large ulcer on the posterior wall of the distal half of the stomach, the base of the ulcer being adherent to the pancreas. The ulcer was 3.5 by 4 cm in diameter, elliptic, almost circular. The fatal bleeding resulted from the erosion of an exposed branch of the splenic artery.¹⁷

A man, aged 35, was struck in the abdomen by the hoof of a horse. A few days later, vomiting began. Symptoms continued with increasing severity for one year, at which time a gastro-enterostomy was performed for a pyloric ulcer. A cure resulted.¹⁸

Kronlein's¹⁹ rather remarkable and striking case is probably the first in which a duodenal ulcer was described as following an injury.

A man aged 24, an equestrian, was violently thrown over the saddle of his horse, the abdomen striking with violence the pommel. Twenty-four hours later the patient began to experience violent postdigestive pains. Four weeks later, vomiting was added to his symptoms. However the symptoms were alleviated for a short period of weeks only to recur with severity and with increased loss of weight.

Four months after the accident, the patient came under the observation of Kronlein. There was marked epigastric tenderness and evidence of gastric dilatation with probable pyloric stenosis. As much as 3 liters was vomited at one period, at times with the presence of free acid, at other times when coffee-ground material was obviously present without free acidity. The patient was operated on eight months after the trauma. A stenosing, cicatrizing ulcer of the pylorus adherent to the liver, was demonstrated at laparotomy. A resection of the pylorus was undertaken, but death resulted. At autopsy a round ulcer of the duodenum was observed, causing a marked stenosis of the duodenal lumen.

A second case by this author¹⁰ bears similar testimony to the existence of a post-traumatic cicatrizing ulcer.

A man aged 48 was struck in the abdomen by the handle of a pitchfork. Severe pain began within twenty-four hours. Three months later protracted vomiting occurred with loss of appetite and emaciation. At operation a dilatation of the stomach was seen with white areas of scar tissue in the pyloric region. On the suspicion of carcinoma, a resection was performed, the resected specimen, however, showing only the cicatrix of a healing pyloric ulcer.

A man, aged 40, three and one-half years after a powerful kick in the left hypochondrium and after a prolonged period of gastric distress and vomiting, underwent an exploratory laparotomy. A gastro-enterostomy was performed for an ulcer adherent to the inferior surface of the liver, the anterior surface of the body of the stomach was adherent also to the anterior abdominal wall.²⁰

The case of Abercrombie,²¹ a report of which was published as early as 1824, deserves due consideration.

A woman was kicked in the abdomen by a horse. An inflammatory tender area in the upper part of the abdomen was present for some time but suddenly disappeared during an

attack of coughing. Severe diarrhea was followed, after a time, by death. At autopsy there was noted a perforated ulcer of the lesser curvature of the stomach adherent to the liver, the site of a fistula connecting the wall of the stomach with the ileum. The sudden change in the course of the symptoms was thus to be explained on the basis of a sudden rupture of a perforating ulcer with abscess into the lumen of the ileum.

Wendel²² cites the case of a man who sustained a violent fall on the abdomen. After a protracted course of four years, cure resulted following a gastro-enterostomy for a stenosing pyloric ulcer.

While the pylorus seems most often to be the site of the ulcer, the lesser curvature ranks next in frequency. The following case is a little unusual.

A man aged 35, sustained an abdominal injury, which was followed by symptoms of ulcer for one and a half years. There had been no previous gastric complaints. The usual vomiting and hematemesis finally ensued. At operation an inflammatory mass occupied the lesser curvature, four fingerbreadths from the pylorus. This mass consisted of a fistulous tract leading from the base of an ulcer through inflammatory tissue with numerous small abscesses to the bed of the liver.²³

The case of Pauly¹² is cited and discussed by Stern as an ulcer occurring as a result of a violent throw backward on the part of a man to prevent a fall. Six weeks later a duodenal ulcer perforated with fatal issue. Though the patient had always been absolutely well before the fall, Stern, who is very critical, tends to accept the case as one of traumatic ulcer, though with some hesitation.

CASES SUSTAINED BY ROENTGENOGRAPHIC DEMONSTRATION OF ULCER

Stern⁸ further accepts without reservations two cases in which the roentgenographic evidence of an ulcer forms the substantiating evidence. In one case, that of O. Gross, a lesser curvature niche was seen fifteen months after the injury. In the second case, a penetrating duodenal ulcer with niche formation was roentgenographically observed two years after the injury.

COMMENT

While this article is not intended in any way to include a comprehensive review of all the cases in the literature, sufficient striking and illustrative cases have been cited to demonstrate the outstanding characteristics of the etiology, pathology and clinical course of a traumatic ulcer.

ETIOLOGY

From the standpoint of etiology, it will readily be seen that cases in men far outnumber those in women as can easily be assumed, day laborers and artisans employed in the more strenuous occupations being exposed more freely to accidents. The trauma is always of the severe type, falls, violent compression injuries and vehicular accidents, blows from falling bodies and from projecting objects predominating. There is an immediate period of shock, followed within a short time (from twenty-four hours to a few days, at most, weeks) by the onset of symptoms.

Occasionally the violence involves a portion of the body distant from the abdomen, the indirect force acting along the principles of contrecoup. In more instances the posterior wall of the stomach has been lacerated by falls on the spine, or by explosions. Such an unusual mechanism is illustrated in the case of Thiery²⁴ in which a man fell 24 feet, landing on his buttocks, the injury resulting in an ulceration of the gastric mucosa. Occasional cases have been cited in

which the violence of abdominal wall contractions are so severe, as in attempting to save oneself from a fall, that the mucosa of the stomach is bruised by the strenuous muscle effort, or, as in a case cited, of the man lifting a heavy cask of wine

PATHOLOGY

The pathologic changes that result from the injury are probably at first merely submucosal or mucosal hemorrhages, with lacerations of the walls of the stomach of various degrees of severity. After the short preliminary or incubation period, the symptoms point to the formation of a true peptic ulceration occupying the seat of the trauma and caused, presumably, by the peptic digestion of the lacerated and blood-suffused mucosal tissue. Such ulceration occurs with great rapidity, apparently within a few hours or, at most, a few days.

Traumatic ulcers are usually single, occasionally, as in the case cited by Fertig,¹⁸ three gastric ulcers were seen all in the same line along the magenstrasse or lesser curvature groove, one of which had opened the coronary artery of the stomach. The form of the ulcer is variable, it may be circular, elliptic or oval. The dimension varies from 0.5 cm to 5 or 6 cm in diameter. The ulcer does not necessarily occupy the whole extent of the traumatic tear. In the case of Potain,¹⁹ the cicatrix extended almost half across the organ, though the ulcer occupied only the lesser curvature of the tear.

Microscopically, the fully developed traumatic ulcer differs in no way from the usual peptic ulcer.

The site of the ulcer is frequently the pylorus, often the lesser curvature, and occasionally the surfaces of the anterior or posterior walls of the antrum or body of the stomach. In this respect traumatic ulcers follow the statistics for distribution of the usual peptic ulcer not necessarily that these sites are more often exposed to the trauma but because these are the areas of the stomach where, according to the theory of Aschoff,²⁰ minor traumas, such as occur from rough food or chemical injuries, result in ulcer formation.

A more obvious explanation is also plausible, for it is the antrum and the lesser curvature of the antral region that are exposed to injuries, since these areas of the stomach underlie the exposed epigastric angle of the abdominal wall. The pylorus, lying deeper and more to the right, is less exposed but more liable to be compressed against the vertebral column as a result of a crushing blow or fall. The great tendency of the pyloric ulcer to cause stenosis is easily understandable, as here there is not only the customary tendency of pyloric ulcer to cicatrize with stenosis but also the factor of the fibrous healing of the traumatized pyloric tissues incident to the original injury.

The duodenum as the site of traumatic ulcer seems far outnumbered by the stomach. This is easily explained on two grounds. The duodenum is better protected from direct injury by its deep placement and attachment to the right border of the vertebral column opposite the first and second lumbar vertebrae. In this site it is sheltered by the broad projecting bulk of the bodies of the vertebrae and can be reached only by a very direct and insinuating blow or object. In the second instance, the earlier literature fails to recognize duodenal ulceration, since before the publications of Moynihan in 1903 the existence of duodenal ulcers was practically overlooked. It is for this reason that statis-

tical comparison of the relative frequency of gastric versus duodenal lesions must be inaccurate.

In addition to the ulcer itself, the pathologic descriptions deal with perforations of the ulcer bed and adhesions to the pancreas, liver or abdominal walls, fistulous tracts incident to chronic perforating ulcers, and abscesses and forms of localized peritonitis as well as occasional gastrocolic and gastrojejunal fistulas are also cited as complications of traumatic ulcer.

Gastric acidity or the existence of free hydrochloric acid in the stomach contents seems a constant factor in all the literature, wherever the analysis of gastric contents is mentioned, free acid and high degrees of total acidity are always quoted. There are no instances of anacid traumatic ulcers.

SYMPTOMATOLOGY AND COURSE

The onset of the digestive symptoms corresponds to the formation of the peptic ulceration. The symptoms are usually initiated by pain and vomiting, hematemesis occurring early in the course or with the first bouts of vomiting. Sometimes hematemesis is delayed, occurring only weeks or months later in the course. All the cases are characterized by emesis of blood or by melena, for hemorrhage seems to be a constant report in the literature, either because it is a constant phenomenon or because no author will report a case without this confirmatory and pathognomonic symptom. In general, the clinical course of the case resembles in all its features that of the customary peptic ulcer. Periodicity is an outstanding feature, though the usual seasonal variations and recurrences have not been noted. The cases seem to run a more severe course, however frequently being accompanied by those more serious complications associated with ulcer such as perforation, hemorrhage, pyloric stenosis, and hour-glass deformity.

The progressive downward course in the more serious and fatal cases is characterized by protracted vomiting, loss of weight and flesh, anemia, and severe emaciation. Many of the cases have come to operation, gastro-enterostomy being the procedure of choice since most of the operative indications have been predicated on the pyloric stenosis, which is so common a complication.

Malignant degeneration of traumatic ulcer has not been observed.

PROGNOSIS

Little may be said on the subject of prognosis. It is obvious that only the more severe cases are reported in medical writings. The milder cases have been occasionally reported, but, resulting in spontaneous cure are subjected to the criticism that the ulcer had not been demonstrated or proved beyond a reasonable doubt. With the free use of roentgenography, it seems likely that more cases of the less severe and nonfatal type will be increasingly reported.

Does mild trauma play any important role in the formation of the usual peptic ulcer? Various authors have reported trauma as an etiologic factor in groups of accumulated ulcer statistics.

Thus, Mattison²⁶ reports twenty-five cases of traumatic ulcer and states that in his opinion 15 per cent of all peptic ulcers have some relative traumatic insult before the onset of symptoms. Friedenwald,²⁷ in 200 collected cases of peptic ulcer, found a history of trauma to the abdomen in 2 per cent of the series.

²⁵ Aschoff L. *Lectures on Pathology*. New York, Paul B. Hoeber Inc. 1924.

²⁶ Mattison K. *Traumatic Gastric Ulcer*. *Hygica* 86: 370 (June 15) 1924.

²⁷ Friedenwald Julius. In discussion on Jordan Sara M. and Kiefer E. D. *Am J Surg* 15: 472 (March) 1932.

Hurst²⁸ states that from time to time there is a close connection between trauma and the development of a gastric ulcer, though he quotes no percentages. Einhorn²⁹ makes a similar observation.

The thought is thrown out merely as a suggestion that perhaps mild traumas have been overlooked in the anamnesis of ulcer cases, given an ulcer constitution and chemism, may not seemingly mild trauma be a more frequent deciding etiologic factor than has hitherto been admitted?

CRITICAL SUMMARY

Liniger and Molineus³⁰ have specified certain postulates that need to be satisfied before a case of suspected traumatic ulcer may be accepted as a true example of such a lesion.

- 1 Proof must be given of the absolute absence of gastrointestinal complaints or symptoms prior to the accident.
- 2 The trauma must be a severe one and localized to the abdominal wall, preferably to the epigastrium.
- 3 The immediate onset of symptoms must follow the injury.
- 4 The continuation of the developing symptoms and signs must assume the characteristics of a true gastric or duodenal ulcer.

Judged by these postulates, it seems impossible to escape the conclusion that traumatic ulcer of the stomach and duodenum does exist. While it is likely that some or even many of the cases quoted in the earlier foreign literature may be instances of lacerations or contusions of the gastric mucosa rather than of true ulcers, yet a large majority of the citations refer to cases that answer all the postulates and may be accepted in good faith as characteristic specimens of ulcers.

The subject of traumatic peptic ulcer has great medico-legal importance. Much depends, in compensation cases of this type, on the evidence of expert witnesses and authorities. It behooves those that occupy such a position in the medical community of this country to acquaint themselves with the literature and with the facts, the better to be able to judge of the statements and evidence of opposing witnesses and lawyers in the interests of justice. The complainant should not be deprived of fair compensation because of ignorance of the facts on the part of the medical expert who is called on to answer the usual "hypothetical" question, nor should a malingerer be allowed to set up a false claim that cannot be intelligently rebutted by the experience and wisdom of learned medical authorities.

30 Liniger and Molineus quoted by Kessler H. H. *Accidental Injuries*, Philadelphia: Lea & Febiger, 1931.

The General Practitioner and Therapeutics—Medical students ought to be taught therapeutics just as thoroughly as they are now taught diagnosis or pathology. In connection with this one might have reason to hope that the general practitioner, who has ample opportunities for observing the therapeutic effects of drugs, might play a more important part in the advance of therapeutics than he has done for the last hundred years. Many observant general practitioners find out, as the result of their experiences, points about the effects of drugs or their side actions which may seem too insignificant to warrant publication. Though these points taken singly may seem of little importance, taken in the aggregate the experiences of the general practitioner, if they could be collected and assessed, would certainly assist greatly in the advance of practical therapeutics—Gunn, J. A. *Remarks on the Outlook of Research in Therapeutics*, *Brit. M. J.* 2:391 (Aug. 27) 1932.

THE TREATMENT OF AMEBIASIS WITH IODOCHLORHYDROXYQUINOLINE (VIOFORM N N R)

N. A. DAVID, M.D.

H. G. JOHNSTONE, Ph.D.

A. C. REED, M.D.

AND

C. D. LEAKE, Ph.D.

SAN FRANCISCO

Chiniofon N N R, which is sodium iodo-hydroxy-quinolinesulphonate, has been widely exploited under various trademarked names ("yatren," "anayodin") as a relatively nontoxic and supposedly efficient amebicide. It is amazing that there was until recently, so little critical experimental or clinical study of this compound, especially in comparison with other halogenated oxyquinolines, of which there are many. Why was iodo-hydroxyquinoline selected for clinical exploitation from those halogenated oxyquinolines available for study when no evidence was furnished that it has demonstrable advantages over the others?

EXPERIMENTAL DATA ON IODOCHLORHYDROXY- QUINOLINE

As part of a comprehensive survey of the chemotherapy of amebiasis,¹ this compound was compared with hydroxyquinoline and certain of its halogenated

TABLE 1—Comparison of Biologic Activity of Iodochlorhydroxyquinoline (Vioform N N R) with Sodium Iodo-hydroxyquinolinesulphonate (Chiniofon N N R)

Biologic Activity	Iodochlorhydroxyquinoline	Chiniofon
Toxicity in guinea pigs on single oral administration	200 mg. per Kg. kills 18/20 guinea pigs within 4 days	600 mg. per Kg. kills 7/15 guinea pigs within 6 days
In vitro amebicidal concentration in 24 hours	Soluble HCl concn pound 1 10 000	1 500
Balantidicidal activity in naturally infected guinea pigs	Cured 80% at divided total dosage of 150 mg. per Kg. with 20% mortality	Cured 60% at divided total dosage of 600 mg. per Kg. with 40% mortality
Amebicidal effect in naturally infected macaques	Cured 7/8 at 100 mg. per Kg. for 10 days	Cured 2 at 500 mg. daily for 28 days. Killed 2 at 2 Gm. daily for 10 days (J. F. Kessel)

derivatives from the standpoint of oral toxicity in guinea-pigs and cats, amebicidal action in vitro, and balantidicidal effect in naturally infested guinea-pigs. We noted an increase in toxicity with increasing halogenation of oxyquinoline and in proportion to the atomic weight of the halogen and a comparable increase in balantidicidal efficiency. A similar relation could not be established, however, with respect to amebicidal action in vitro. Of some eleven halogenated hydroxyquinolines examined we concluded that iodochlorhydroxyquinoline was the most promising of the group for further study with the possible exception of diodo-

This report is based on part of an extended cooperative study of the chemotherapy of amebiasis conducted by the Pacific Institute of Tropical Medicine within the Hooper Foundation for Medical Research and the Pharmacological Laboratory of the University of California Medical School, San Francisco and supported in part by Eli Lilly & Co., Indianapolis and the Ciba Company, Inc., New York. Dr. L. L. Stanley permitted work at the San Quentin Prison and cooperated in carrying it on.
1 Leake, C. D. *Chemotherapy of Amebiasis*. J. A. M. A. 98:195 (Jan. 16) 1932.

hydroxyquinoline, which is still under investigation. This confirmed a preliminary survey, the data on which have been published.² In monkeys naturally infested with *Endamoeba histolytica* iodochlorhydroxyquinoline was found to be more effective in nontoxic doses in completely and permanently clearing the stools than any mode of treatment yet reported on.³ Its superiority to chiniofon N N R is indicated by the summarized data offered in table 1. On the basis of this evidence, we felt justified in making a critical clinical study of the effectiveness of iodochlorhydroxyquinoline in human amebiasis, especially since so many competent observers have reported good results with chiniofon,⁴ although our clinical experience with the latter has been disappointing.

Iodochlorhydroxyquinoline is described in New and Nonofficial Remedies under the name "vioform" as an iodine containing dusting powder proposed as a substitute for iodoform.⁵ It is a grayish-yellow powder with a faint aromatic odor, almost insoluble in water, sparingly soluble in alcohol but soluble in hot glacial acetic acid. It contains about 40 per cent iodine in comparison with 26 per cent in chiniofon, in addition to about 12 per cent chlorine. Some absorption of this drug occurs from the gastro-enteric tract, and it is excreted in part in the urine.

DO dosage

For our dosage in human amebiasis we decided to begin with about one-tenth the dosage we found effective without any evidence of toxicity in monkey amebiasis. This averaged 0.75 Gm daily on the basis of 10 mg per kilogram for a 75 Kg person and was conveniently administered in capsules of 0.25 Gm each, given three times a day. We believe that twice this amount could be tolerated by the average individual without danger. As we found that 0.75 Gm daily for ten days, a total of 7.5 Gm, was not uniformly effective, we gave most of our patients a second such course of therapy after a rest period of a week to ten days following the first. This double course of iodochlorhydroxyquinoline therapy we found successful, as our data herewith reported indicate. We recommend that this dosage be used in chronic amebiasis cases without dysentery but that higher dosages be employed for severe cases.

UNTOWARD EFFECTS

With this course of treatment (0.75 Gm daily for ten days followed by a week's rest, after which 0.75 Gm daily was repeated for another ten days, for a total of 15 Gm in four weeks), we found no signs of toxicity nor unpleasant symptoms in any patient. Usually the patient's stools hardened after three or four days' treatment, and some constipation was noted. The stools presented a characteristic oily green appearance. Thus

may be used as an index of whether or not the patient takes the drug.

In rabbits killed by air injection after the oral administration of 100 mg per kilogram for ten days Dr James Rinehart of the Pathological laboratory of the

fatty infiltration and small necrotic areas were noted in the liver, and also some injury to the renal tubules was seen. These observations suggested that we watch our patients carefully for any indication of liver or kidney damage during and after iodochlorhydroxyquinoline therapy. We found no evidence of such injury in any case, however.

SOURCE OF PATIENTS TREATED

Two separate groups of patients, found infected with *E. histolytica*, have been treated with iodochlorhydroxyquinoline and observed over a considerable length of time. Since the conditions varied under which each group was treated, they are stated here, since more success in treatment was obtained with one group than with the other.

The first group (cases 1-17, table 2) comprised those seen in the outpatient departments of Mary's Help Hospital and the University of California Medical School in San Francisco. Four Filipinos are included who, although not clinic patients, worked in the university hospital and were found to harbor *E. histolytica* on routine examination. These patients were given the drug to take at home according to explicit directions, but some of them failed to follow their instructions properly.

The second group (cases 18-47, table 2) comprised a number of inmates at San Quentin Penitentiary found on the routine examination of new entrants to harbor *E. histolytica*.⁶ These were treated under ideal conditions and probably for this reason our results were better. The drug was given in capsules to each man, who was required to swallow them in the presence of a trusted prison pharmacist. The likelihood of reinfection through infected food handlers in the prison we believe was practically eliminated, since early in our work at San Quentin a thorough survey of the mess force was made and men found harboring *E. histolytica* were changed to other positions and treated. In the San Quentin group a more satisfactory post-therapeutic stool follow-up was possible than in the clinic group.

THERAPEUTIC RESULTS

The data on the results of our treatment of forty-seven amebiasis patients by means of iodochlorhydroxyquinoline are summarized in table 2. Most of the patients received between 200 and 250 mg. of the drug per kilogram of body weight within about thirty days. The smallest effective dose was 120 mg. per kilogram in ten days in a 5 year old child (patient 2). The largest total dose was 600 mg. per kilogram in four and one-half months in an 18 year old Filipino (patient 12). Our criteria for the clinical effectiveness of antiamebic therapy have already been discussed.⁷

By reference to table 2 it may be noted that we had much greater recurrence of infection among the clinic patients (cases 1-17) than among the prison group (cases 18-47). We believe that this was due not so much to lack of effectiveness of the drug as to reinfection from relatives and friends not under observation or treatment, or to other unhygienic environmental factors difficult to control. The prison patients were under ideal control so far as possibility of reinfection was concerned, and it is significant that no recurrences of amebas have been found in this group on frequent stool

examination for several months after the treatment was stopped.

A satisfactory follow-up was carried out in all but four patients (12, 14, 15 and 16), who went to sea within a month after cessation of the treatment. Recurrences of amebas in the stools were noted in six of the clinic patients (1, 8, 10, 11, 12 and 13) within one to four months after drug administration was stopped. We have good evidence to believe that these were definite reinfections due to unhygienic environmental factors beyond our control. In one patient only (patient 26) the stools remained positive for *E. histolytica* during the first course of therapy with iodochlorhydroxyquinoline, but they cleared during a second course of treatment with a slightly higher dose and remained so.

Our results clearly indicate the importance of proper hygienic control of environmental factors in evaluating antiamebic therapy. When such control is possible, iodochlorhydroxyquinoline in the dosage used and recommended by us is a safe and very effective drug with which to treat human amebiasis.

CONCURRENT INFECTIONS

We found a total of thirty-two concurrent infections of *E. nana*, twenty-five of *E. coli*, nine of *Iodamoeba*, four of *Chilomastix*, ten of *Giardia*, and one each of *Enteromonas* and *Trichomonas*, as well as two combined infestations with hookworm and trichuris (cases 13 and 16).

Following treatment, there were twenty infections of *E. nana*, of which twelve were cases discovered during the follow-up examination and eight were cases unaffected by treatment. Similarly, five cases of *Giardia* were discovered after treatment, while of the five cases found before, only one failed to clear. Five cases of *E. coli* were discovered after treatment, while of the twenty previously found, all but four were eliminated by the drug. Of the nine cases of *Iodamoeba* and four of *Chilomastix*, only one each remained after treatment. *Enteromonas* in patient 4 was discovered after treatment. From these results it appears that iodochlorhydroxyquinoline may act as a protozoacidal agent in common intestinal infestations with the exception of *E. nana* and *Giardia*.

OTHER TREATMENT

Six of our forty-seven patients had previously been treated for amebiasis, but unsuccessfully. All six (1, 4, 7, 15, 46 and 47) had received emetine in full recommended doses with only temporary relief. Patient 7 had sixteen doses of emetine each of 60 mg. intravenously, followed by a total dose of 200 tablets of bismuth emetine iodide. Since the stools remained positive, he was given, six months later, another course of emetine therapy of nine intravenous injections of 60 mg. each. The stools, however, continued to contain *E. histolytica* until therapy with iodochlorhydroxyquinoline was instituted. Three patients (1, 46 and 47) had been treated by us previously with a variety of antiamebic agents, including emetine, acetarsone, chiniofon and carbarsone, but with unsatisfactory results. Patient 1, however, was uncooperative and continually exposed to reinfection. Two patients (25 and 26) were treated with arsphenamine for syphilis during the course of antiamebic therapy with iodochlorhydroxyquinoline.

SUMMARY

The clinical trial of iodochlorhydroxyquinoline (Vioform N N R) in human amebiasis is justified on

6 Johnstone H. C., David, N. A. and Reed, A. C. A Protozoal Survey of One Thousand Prisoners, with Clinical Data on Ninety Two Cases of Amebiasis. J. A. M. A. 100: 728 (March 11) 1933.
7 Reed, A. C., Anderson, H. H., David, N. A. and Leake, C. D. Carbarsone in the Treatment of Amebiasis. J. A. M. A. 98: 189 (Jan 16) 1932.

the results of its experimental chemotherapeutic comparison with sodium iodohydroxyquinolinesulphonate (Chimofon N N R). A total dose of 15 Gm given orally in two courses of 0.75 Gm daily for ten days with a week's rest period between appears to be effective in clearing the stools of *E. histolytica* in the average case of human amebiasis. The drug is conveniently dispensed in capsules of 0.25 Gm each.

In forty-seven unselected cases of human amebiasis, iodochlorhydroxyquinoline in the dosage recommended resulted in clinical "cure" in thirty-eight cases, as determined by frequent stool examination during a follow-up period of from three to six months. Six recurrences were found in seven patients subjected to continued danger of reinfection from infected friends or relatives refusing treatment. Three patients could not be followed longer than one month after treatment was stopped, but during this period their stools were free from amebas. No evidence of toxicity from the drug was noted in any patient.

STUDIES IN CRETINISM AND HYPOTHYROIDISM IN CHILDHOOD

I BLOOD CHOLESTEROL

I P BRONSTEIN, MD
CHICAGO

This study on the basis of blood cholesterol has as its objective, first, the establishment of an additional method for regulating thyroid therapy and, second, an improved understanding of the clinical course of the thyroid deficient child. As these children are followed from month to month, it is apparent that the basal metabolic rate, as ordinarily determined by present methods in young children, is unreliable. The basal metabolic rate although valuable, is not a specific test and, as Du Bois¹ indicated in cretinism, the comparison with normal standards often presents great difficulties. The basal metabolic rate, therefore, should not be the principal guide in the progress of these patients. Furthermore, clinical impressions have many limitations.

In searching for an additional aid in determining the dosage of thyroid medication to a less empirical extent and the progress and prognosis in the thyroid deficient child, I had my attention called to the work done at the Lahey Clinic² with hypothyroidism and hyperthyroidism in adults.

The Boston investigators saw the advisability of getting a further laboratory aid to check on the severity of hypothyroidism or hyperthyroidism, since the basal metabolic rate did not always give a true picture, and the clinical impression was difficult to define. They found that patients with rates of —25 and cholesterol values of over 200 were benefited by thyroid medication. A striking relationship between hypothyroidism, blood cholesterol, basal metabolic rate and clinical improvement was observed.

In 1922, Epstein and Lande,³ studying thyroid disorders, found low cholesterol values in hyperthyroidism and high values in hypothyroidism. These observa-

tions had experimental support, for when thyroidectomy was done in hyperthyroidism the blood cholesterol rose in value. In hypothyroidism, on the other hand, the administration of thyroid orally or thyroxine parenterally caused a fall in cholesterol.

Epstein attempted to demonstrate the existence of an inverse relationship between blood cholesterol and the basal metabolic rate. Such relationship was suggested to him because in nephrosis the cholesterol is high and the basal metabolic rate is low. That a definite inverse relationship exists is supported by the views of many workers.⁴

At the Lahey Clinic, forty-seven adults with hyperthyroidism and twenty-three with hypothyroidism were studied. In the former, the average cholesterol was 130 and the basal metabolic rate 51 plus. In the latter, the average cholesterol was 230 and the basal metabolic rate, —30. They concluded from their study that cholesterol reflected better the severity of hypothyroidism and the true clinical condition than does the basal metabolic rate.

French investigators⁵ brought about a return of the blood cholesterol values to normal by means of thyroid preparations in clinical patients with hypercholesteremia. Many other investigators⁶ found diminished values of cholesterol in exophthalmic goiter and the return to normal of this blood lipid following proper surgical or medical treatment. Likewise, these workers obtained increased values of blood cholesterol in thyroid insufficiency.

Contradictory reports are also available,⁷ particularly as applicable to hyperthyroidism. Gextman,⁸ from extensive studies in this field, concludes that the relationship between the basal metabolic rate and the cholesterol is true only in extreme cases of hyperthyroidism. Luden,⁹ in thirty-five instances of exophthalmic goiter, found the cholesterol value to be within normal even when the basal metabolic rate was 100 plus.

Rabinowitch,¹⁰ after a study based on 2,000 observations in 385 cases of diabetes mellitus, felt that the blood cholesterol was of greater value and more accurate than blood sugar as prognosticating the seriousness of the diabetes. The estimation of this so-called lipid, which is a relatively stable compound, is simple.¹¹

Sure and Smith¹² found lipemia in experiments with vitamin B deficiency and felt that the chemical study of the blood lipids might serve as a yardstick by which to measure this avitaminosis.

Similarly, can cholesterol be regarded as an aid in the diagnosis of cretinism and hypothyroidism in childhood and as a guide to therapy?

Mindful that the exact mechanism regulating cholesterol metabolism is obscure, this investigation was undertaken for the purpose of determining the blood cholesterol relationship in thyroid deficient children, with the possibility of its use as a corroborating test in controlling thyroid dosage and maintaining metabolism at a normal level.

To establish an average blood cholesterol for the group considered in this paper, the values¹³ of this lipid were determined in twenty hospitalized and five ambulatory children, ranging in age from 2 months to 11 years, twelve of these were boys, and thirteen, girls. Twelve of these patients were under 4 years and, of these, six were under 1 year. The determinations excluded nephrosis, nephritis, diabetes mellitus, purpuras, anemias and blood dyscrasias, as well as other diseases in which cholesterol metabolism may be definitely altered. The average level of blood cholesterol in this group was 190 plus, the highest value was 217 in three instances, the lowest 129.

Boyd¹⁴ regards any values in excess of 200 as indicative of hypercholesteremia. Leopold¹⁵ in thirty-five normal children ranging in age from 3 to 12 years, found an average blood cholesterol of 173. Rabinowitch, in forty-four children under 14 years of age, found the blood cholesterol values to be similar in range to those found in normal adults. McEachern and Gilmour¹⁶ found in twenty-eight adults the normal values to range between 130 and 200 mg. The literature¹⁷ includes many other reports of blood cholesterol in infants and older children.

Hypercholesteremia is existent in the children in this study. Of the present series, eight are boys and four are girls, ranging in age from 3 months to 16 years. The highest cholesterol values in these children when they were not receiving thyroid varied as follows: 277, the lowest, in the 4 month old male cretin, from 312 to 384 in five, 416 to 454 in three, 625 in one, and 782, the highest reading, in the 13 year old female cretin. In one of the patients the cholesterol was not obtained, since the child was in the hospital before the present study. At no time would his parents allow the withdrawal of thyroid for a short period to determine the cholesterol when not under treatment. This boy had on admission three epiphyseal centers and, in less than one year under therapy, eight epiphyseal centers appeared.

The average cholesterol value of our group under treatment is 171, the only determination above 200 being in J. S., a boy, aged 3½ years, whose carpal bones showed at the onset of treatment ossification equivalent to a 1 year old child. It was impossible to obtain a basal metabolic rate of sufficient accuracy and satisfaction in this patient. He had received three-fourths grain (0.05 Gm.) of thyroid a day prior to admittance, at which time his cholesterol was 227. After several weeks without thyroid, his cholesterol rose to 313, and when he received treatment the cholesterol fell 96 points.

When it is impossible to obtain basal metabolic rates in older children, owing to unmanageability, or in infants because of lack of enclosed respiratory chambers, cholesterol determinations may serve as contributory aids.

This was demonstrated in M. B., a boy, aged 4 months, in whom we were unable to determine the basal metabolism. He entered the hospital with a cholesterol of 156, having received medication at another institution. The patient possessed a suggestive facies, macroglossia and a characteristic croak. After a short period without thyroid, the cholesterol rose to 277. Since at first there was slight uncertainty as to his being a cretin the rise in cholesterol helped the decision, and at present he presents features diagnostic of thyroid deficiency.

It should be borne in mind that the majority of these children were under treatment before this study began and as it is impossible to keep these children off thyroid for too long periods without serious parental objections these cholesterol determinations may not represent the maximum high values. However, merely keeping thyroid away for short periods in a previously treated child with low cholesterol brings not only a return of hypothyroid characteristics but a definite rise of cholesterol as well.

G. M., a boy, aged 9½ years, had been under treatment previous to the undertaking of this study. It was not quite clear that he was a cretin, but after two months without treatment he presented typical characteristics.

April 12, 1932 up to which time he had been receiving from 2 to 3 grains (0.13 to 0.2 Gm.) of thyroid a day, it was decided to stop thyroid. At this time his cholesterol was 156, the basal metabolic rate was plus 47, the pulse 94, and the weight 58¾ pounds (26.6 Kg.). In the two months that thyroid was withheld, his weight rose to 65¾ pounds (29.5 Kg.), a gain of 6¾ pounds. The cholesterol rose to 454, a change of 298 points, the basal metabolic rate fell 58 points, and the pulse fell 40 points. When thyroid (2 grains daily) was started, the cholesterol fell to 172, a change of 282 points, the basal metabolic rate rose 48 points, the pulse rose 42 points and he lost 5¾ pounds. After the two months without medication, the hair had grown coarse and the abdomen large, and myxedema appeared.

Without becoming involved in speculation as to the cause for the excess of this so-called lipid, it might be said that a relationship exists between cholesterol, the basal metabolic rate, and thyroid dosage. For the purpose of ascertaining whether a definite quantitative relationship can be demonstrated, two cretins are now being studied and will be the subject of another paper.

A. B., a boy, aged 13, entered the hospital with a cholesterol of 454 and a basal metabolic rate of -41. The bony development of the wrist was that of a 5 year old child. In fifteen days on approximately 1 grain (0.065 Gm.) of thyroid daily, the cholesterol fell to 200 and the basal metabolic rate rose to 0.

At this time I was interested in the possibility of influencing cretins by other means, as for example insulin, as suggested by Chamberlain,¹⁸ since insulin will diminish the hypercholesteremia in diabetes. The pancreatic hormone was used for forty-three days, during which period thyroid was stopped. The cholesterol rose from 200 to 454 and the basal metabolic rate fell from 0 to -35. When thyroid was again instituted the cholesterol fell to 208, a fall of 246 points,

and the basal metabolic rate gradually rose 71 points. In the course of a little over two weeks the thyroid was rapidly increased from 1 to 8 grains (0.065 to 0.5 Gm) and the patient was kept on this large dose for a short period following which improvement in his appearance and mental reaction took place.

The relationship between cholesterol and the basal metabolic rate is further shown by J. F., a boy, who, Feb. 12, 1932, had a cholesterol value of 143 and a basal metabolic rate of plus 69. This child returned, April 30, after an absence of eleven weeks during which time he had received 3 grains of thyroid for seven weeks, $1\frac{1}{2}$ grains (0.1 Gm) for two weeks while ill with chickenpox, and no thyroid for another period of two weeks. The cholesterol now was 238, having risen 95 points, and the basal metabolic rate was —3, a fall of 72 points. In addition to the cholesterol rise and the basal metabolism fall the abdomen had enlarged, the hair was coarse, and the boy was sluggish, symptoms not present eleven weeks earlier.

Incidentally, as work goes along with this interesting substance many problems arise, as for instance the determination of a maximum amount of thyroid beyond which it is useless to proceed, because improvement has reached its physiologic limit. J. F. exemplifies this, as he seemed to do just as well on 2 grains of thyroid as on 3 grains, although he showed no toxic signs on the increased dosage.

The possible use of blood cholesterol as an index in the regulation of thyroid dosage is evidenced by A. K., a girl, who had been under treatment for one year before the present work was started. She had entered the hospital in October 1930, with an admission cholesterol of 782 and a basal metabolic rate of —6. Thyroid therapy was instituted, starting with three-fourths grain and gradually increasing to 3 grains a day. During her stay in the institution the cholesterol fell to 179 and the basal metabolic rate rose to plus 77. After she left, the thyroid was fed irregularly.

She again came under observation, Oct. 6, 1931, at which time the basal metabolic rate was plus 69, the cholesterol 417, and she was receiving $1\frac{1}{2}$ grains of thyroid daily. She had gained weight, the temperature was subnormal and her parent stated that she was irritable. The high cholesterol value, however, attracted attention, and because of this the thyroid was increased, the basal metabolic rate being disregarded. The result was clinical improvement, with the basal metabolism remaining at the same level, and a fall in cholesterol to 227.

COMMENT

A relationship exists between hypercholesteremia and hypothyroidism in adults, as is indicated in a review of the literature. It was undertaken to ascertain the presence of a similar relationship in hypothyroidism of children.

The blood cholesterol was determined in twenty-five children in whom no known derangement of cholesterol metabolism was present, and the average was found to be 190 plus. This value for normal cholesterol is substantiated by the work of other investigators in this field.

Hypercholesteremia was found in the twelve thyroid deficient children studied. The values ranged from 277 to 782. Thyroid therapy definitely lowered the blood cholesterol in the cases cited, in addition to raising the basal metabolic rate and effecting clinical improvement.

It is desirable to have an additional method for the diagnosis and treatment of thyroid deficient children,

particularly in infants and borderline cases. The use of cholesterol as an aid in the diagnosis and regulation of thyroid dosage offers definite possibilities.

A NEW SIGN OF PERICARDIAL EFFUSION

ELI MOSCHCOWITZ, M.D.

NEW YORK

The determination of moderate quantities of fluid within the pericardial cavity by physical diagnosis is too often indecisive. Even the roentgenologic diagnosis is by no means infallible. Of all the evidences that are conventionally employed I have found that the conjunction of three signs is usually conclusive in determining the diagnosis of pericardial effusion in the order of their importance they are (1) widening of the area of cardiac flatness, (2) abrupt transition from pulmonary resonance to cardiac flatness and (3) widening of the cardiac dullness in the second intercostal space. Of these three signs, only the second, so far as I can gather has not been described before. No one of these signs, taken singly, is conclusive, but together they form a triad which is thoroughly reliable, as confirmed by roentgen examination or at autopsy.

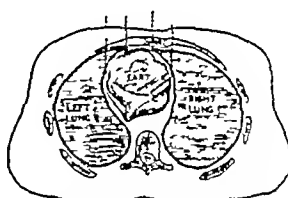

Fig 1—Schematic representation of cross-section of normal chest (After Braune, C. W. *Topographisch anatomischer Atlas* Leipzig: Veit & Co. 1886-1888.)

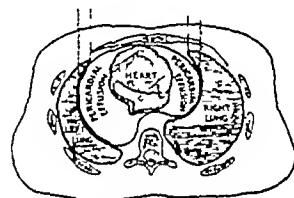

Fig 2—Schematic representation of cross section of chest with pericardial effusion. (After Conner, L. A. *Am. Heart J.* 1: 421-433 [April] 1926.)

The physical basis for these signs is obvious. The normal area of cardiac flatness is comparatively small, it rarely extends beyond the left border of the sternum, and from this line it extends to the left to within 2 cm of the nipple line (fig 1). When the heart is enlarged, this area obviously increases, but even when the heart is greatly enlarged, as for instance in the bovine hearts of aortic insufficiency, the area of flatness rarely attains the size witnessed in pericardial effusions of even moderate grade. On percussion, it is most unusual for an enlarged heart to give a flat sound up to the right border of the sternum into the right side of the chest. The determination of the left outline of the area of cardiac flatness is of less significance. Broadly speaking, therefore, when an area of cardiac flatness extends to the right border of the sternum, a pericardial effusion is suggested.

The abrupt transition of pulmonary resonance to cardiac flatness is due to the practical disappearance of the lung-filled angle between the heart and the anterior wall of the chest owing to the greatly dilated pericardial sac (fig 2).

The acuteness of the angle subtending the border of the lung, on the one hand, and the extreme edge of the pericardial sac, on the other, determines the area of

cardiac dulness, which normally is from about 2 to 3 cm in width. As this angle is almost completely obliterated in pericardial effusions, the normal circumferential zone of cardiac dulness becomes reduced to almost nothing, and the abrupt transition of pulmonary resonance to flatness is the consequence. To determine this sign, deep percussion is essential.

The widening of the cardiac outline in the second intercostal space is merely another evidence that pericardial effusions have a pronounced tendency to accumulate at the base of the pericardial sac. This widening is confirmatory of one of the important diagnostic criteria of pericardial effusions in roentgen diagnosis, namely, the increased widening of the cardiac shadow at the apex of the cardiac triangle.

NICOTINE POISONING BY ABSORPTION THROUGH THE SKIN

JAMES M. FAULKNER, M.D.

BOSTON

Nicotine is one of the most deadly poisons known to man and, at the same time, one with which he comes into most intimate contact in his daily life. It is somewhat surprising, therefore, that serious cases of nicotine poisoning are not reported more frequently. The main reasons for the infrequency of serious poisoning are that the percentage of nicotine in tobacco is too small to make it easy to get a fatal dose from the ingestion of tobacco or the inhalation of its smoke and *that nausea and vomiting are early symptoms which ordinarily prevent further absorption of the drug.* Fatal poisoning from tobacco, although rare, has been reported from smoking, from swallowing tobacco from tobacco enemas, and from its use as a local application to the skin in favus.¹ The commercial insecticides that contain high percentages of nicotine are of course, far more dangerous. McNally² has reported seven fatal cases of nicotine poisoning from the drinking of an insecticide, two of these were accidental, and death occurred within five minutes in each case. The widespread use of nicotine solutions as sprays in greenhouses would lead one to expect cases of poisoning among gardeners. A number of florists of wide experience with whom this was discussed were unanimous in declaring that they had never heard of a case of serious nicotine poisoning. That such may occasionally occur, however, is shown by several recent reports of poisoning in gardeners.

Wilson³ reports an instance of moderately severe nicotine poisoning in two gardeners who had been painting peach trees with a 27 per cent solution of nicotine and in so doing had splashed their hands, forearms and faces with the solution. In these cases absorption apparently took place through the skin.

Fretwurst and Hertz⁴ report a case of mild poisoning in a gardener who was spraying a tree outdoors with a 20 per cent nicotine solution. In addition to the well recognized symptoms of vomiting, prostration and

loss of tendon reflexes, these observers also demonstrated an increase in the blood sugar to 175 mg per hundred cubic centimeters, leukocytosis, and inversion of the T waves in the electrocardiogram. Nicotine was recovered from the urine. In this case absorption was apparently through the lungs.

Lockhart⁵ describes an instance of severe poisoning in a girl employed in the manufacture of a nicotine insecticide. Two drachms (7.5 cc) of a 95 per cent solution of nicotine was spilled on the sleeve of her overalls. She immediately removed the overalls, washed her arm with hot water, wiped off the sleeve, put the overalls on again and returned to work. Twenty minutes later she collapsed. She was pallid, cold, speechless and "practically pulseless." For half an hour she appeared to be on the verge of death but finally recovered. Traces of nicotine were recovered from vomitus obtained three hours later. In this case absorption was clearly through the skin.

The following case is an example of severe nicotine poisoning as a result of absorption through the skin.

A man, aged 35, American, a florist, was seen in consultation for an insurance company, Oct. 24, 1932. His past history was irrelevant except for the fact that he had been in the habit of smoking three or four pipefuls of tobacco daily and that he had frequently used diluted nicotine solutions in spraying plants without serious symptoms. Oct. 4, 1932, he came into contact with a concentrated solution of nicotine in the following manner.

While engaged in doing a light electrical repair job at a work bench he sat down in a chair on the seat of which some 'Nico Fume Liquid' (a 40 per cent solution of free nicotine) had been spilled. He felt the solution wet through his clothes to the skin over the left buttock, an area about the size of the palm of his hand, and recognized what it was by its characteristic odor. He thought nothing further of it, however, and continued at his work for about fifteen minutes, when he was suddenly seized with nausea and faintness. He took a drink of water and immediately vomited and continued to retch. He stepped outdoors and found himself in a drenching sweat. His respirations became labored and painful, a physician was called, and he was sent to a hospital in an ambulance. On the way to the hospital he lost consciousness and did not recover until three hours later. During this period he was described by the intern as being semicomatose, writhing, moaning and having rapid irregular gasping respirations. The heart beat was described as 'very irregular, at a rate of 86 per minute,' the rectal temperature was 95.6 F, and respirations were 40 per minute. The blood pressure was 110 systolic and 45 diastolic. The pupils were pin-point in size. The pulse was feeble and the extremities were cold. No tendon reflexes could be elicited. There was no local skin reaction over the buttock. The urine had a specific gravity of 1.018, with a "slightest possible trace" of albumin, 2 per cent sugar and a large amount of acetone. The urinary sediment showed from three to five white blood cells per high power field but no red blood cells or casts were found. He was given 1 ampule of caffeine sodiobenzoate subcutaneously and kept warm with hot water bottles and blankets. The respirations continued labored throughout the night. Six subsequent urine specimens voided that night and three the next day were negative for sugar.

The following day his symptoms had disappeared except for a feeling of substernal pressure, weakness and slight nausea. The irregularity of the heart continued but caused no subjective symptoms. He was discharged from the hospital on the fourth day. On discharge from the hospital he was given the same clothes that he had worn when he was brought in. The clothes had been kept in a paper bag and according to the patient were still damp where they had been wet with the nicotine solution. Within an hour after leaving the hospital he was again seized with nausea, vomiting, sweating and difficulty in breathing and was readmitted to the hospital. He showed no change in physical signs except for profuse sweating and apparent dysp-

nea. The temperature was 99.6 F, pulse rate 84 and respiration rate 20 per minute. There was no sugar in the urine. He remained in the hospital for four more days. When first seen by me, three weeks after his accident, his symptoms consisted of weakness, sweating, vertigo on change of position, insomnia, nervousness and a mild, constant substernal pressure not aggravated by exertion. All of these symptoms gradually cleared up in the course of the following three weeks, although extrasystoles were constantly present on repeated examinations. Electrocardiograms showed that the extrasystoles were arising from two different foci in the ventricle. The significance of these extrasystoles is not clear. They were still present in undiminished frequency three and one-half months after the poisoning, but they have never produced subjective symptoms and may have been present previously.

The patient appeared to be in the best of health at his last examination three and one-half months after the accident. His only complaint was that he was unable to go into a greenhouse in which the nicotine spray was being used without suffering immediate nausea. He was however able to enjoy five or six pipefuls of tobacco a day so that it does not seem likely that he had become unduly sensitive to the effects of nicotine.

Since reported cases of nicotine poisoning are not common it may not be amiss to point out that this patient's symptoms are quite characteristic of the con-

Skin Absorption of Nicotine Insecticides in Cats

Name	Experiment No.	Weight in Kg.	Dose in Cc.	Symptoms

Black Leaf 40 (40% nicotine sulphate)	1	3.7	10	No effect
	2	3.5	10	No effect
	3	3.5	10	No effect

dition. The classic features are sweating, nausea, vomiting, dyspnea, coma, convulsive seizures, pin-point pupils, a pulse rate that is at first slowed and later accelerated, subnormal temperature, absence of tendon reflexes, polymorphonuclear leukocytosis, increased blood sugar with glycosuria and electrocardiographic signs suggesting a toxic effect on the myocardium. Nicotine may be demonstrated in the urine.

"Nico-Fume Liquid" is, according to the manufacturer, a "forty per cent water solution of commercial (free) nicotine, there being no other substance of an insecticidal nature present than the nicotine."⁶

In the case here cited, poisoning unquestionably occurred by absorption of nicotine through the skin.

While this mechanism has long been recognized by pharmacologists, it does not appear to be regarded as a hazard by florists who use concentrated nicotine solutions extensively as insecticides. Indeed, the containers in which "Nico-Fume Liquid" is sold freely to the public bear no warning as to the dangers of skin absorption. It appeared worth while, therefore to investigate the effect of the application of "Nico-Fume Liquid" to the skin of lower animals.

Five experiments with cats were carried out. The procedure in each instance was as follows:

The unanesthetized animal was fastened on its back to a board. The fur over the lower part of the abdomen was cut short with scissors but the skin was not shaved or traumatized in any way. A measured amount of "Nico-Fume Liquid" was poured on the skin and very gently sopped and rubbed in with the gloved finger to make sure it was in contact with the skin. The area of skin wet with the solution was from 5 to 7 cm in diameter in each case. The wet area was then covered with an inverted glass dish held down tightly with adhesive tape to prevent the fumes from escaping.

The results of the experiments which are briefly summarized in the accompanying table indicate that free nicotine may be readily absorbed through the intact mammalian skin. As little as 3 cc of a 40 per cent solution applied to the skin of a cat may be rapidly fatal. Since nicotine in the form of a solution of nicotine sulphate is also widely used as an insecticide, it seemed advisable to investigate its properties in regard to skin absorption. Accordingly, an insecticide known as "Black Leaf 40" containing 40 per cent of nicotine sulphate was employed in the same manner. Ten cubic centimeters of this solution applied to the cat's abdominal wall produced no effect whatever in three different animals. One of these cats was subsequently exposed in the same way to the same dose of "Nico-Fume Liquid" to which it promptly succumbed. The difference in skin absorption between the solution of free nicotine and the sulphate is in keeping with differences noted in skin absorbability between other alkaloids and their salts.

If concentrated free nicotine solutions are as dangerous as indicated by the experimental work and the clinical case here reported the question arises as to why poisoning is not more frequently encountered. The answer lies in the fact that the concentrated solution has a most offensive odor, appearance and consistency. It is a very dark brown slimy fluid with a peculiarly nauseating odor. For these reasons even a careless person would not allow it to remain in contact with his person except under unusual circumstances, as in this case, in which it would have been necessary for the man to remove his clothes. Furthermore the solutions are ordinarily highly diluted for insecticidal purposes, the concentrated solutions being made up merely for convenience in shipping and handling.

SUMMARY

A case of nicotine poisoning resulted from accidental absorption through the skin of a widely used insecticide containing 40 per cent of free nicotine. In experiments with cats it was found that small amounts of this substance applied to the intact skin were readily absorbed with fatal results. It was observed that a similar insecticide containing 40 per cent of the sulphate salt of nicotine produced no toxic symptoms when applied to the skin of the cat.

RESPIRATORY FAILURE AND THE DRINKER RESPIRATOR IN POLIOMYELITIS

EMIL SMITH, M.D.

BROOKLYN

During and following the epidemic of poliomyelitis in 1931, numerous additions have been made to the literature of this subject. My purpose in this paper, based on a study of thirty-six cases is to record observations made in cases of poliomyelitis culminating in paralysis of the respiratory muscles, to delineate the clinical picture when respiratory paralysis is fully established, to outline the results of treatment with the use of the respirator, and, finally, to describe the indications for removing the patients from the Drinker apparatus.

TYPES OF PARALYSIS AFFECTING THE RESPIRATORY APPARATUS

1 *Ascending Paralysis*—Most of the cases of poliomyelitis leading to respiratory involvement begin with paralysis of one or both of the lower extremities. Thirty-five of the thirty-six patients in this series presented an initial weakness of the lower extremities followed by absent knee jerks and complete flaccidity of these limbs. Several hours later the cremasteric and abdominal reflexes disappeared, and within twenty-four hours the intercostals, the diaphragm and the upper extremities became involved.

2 *Descending Paralysis*—The paralysis may begin with weakness of the shoulder muscles followed by flaccid paralysis of both upper extremities, and within a very short time the diaphragm may become involved. In the last instance, respirations are carried on by the intercostals and the accessory muscles of respiration. When the patient lies quietly in bed and is covered, little respiratory embarrassment may be noted, the color is good, respirations are apparently fair and the alae nasi barely dilate. However, on careful examination one will find the abdomen retracting on inspiration and forced out on expiration. This picture is more pronounced when the patient exerts himself. In one patient, paralysis spread downward and involved the intercostal and abdominal muscles and both lower extremities. The descending type of paralysis is rare.

3 *Ascending-Descending Paralysis*—The paralysis may begin in one lower and one upper extremity. Gradually, both upper and both lower extremities become involved, and the infection continues to spread downward and upward simultaneously, ultimately producing intercostal, diaphragmatic and abdominal paralysis. The ascending-descending type of paralysis is also rare and comprises one case in this series.

RESPIRATORY PARALYSIS FULLY ESTABLISHED RESPIRATOR INDICATED

The clinical picture changes the child lies in bed motionless, the eyes have a fearful stare, the face is dusky, the lips are cyanotic, the alae nasi dilate with every inspiration, the accessory muscles of respiration, especially the sternocleidomastoid, become visible with every inspiration, speech is difficult, quick and whispered, the sentences are short and broken up by inspirations between words and occasionally between

syllables, respirations are extremely shallow, the chest and the abdomen are practically vibrationless, the temperature steadily rises and may attain 105 F, the pulse progressively mounts, the child perspires freely, sleep is impossible and the patient may remain awake for days, growing weaker by the hour. If respirator aid is not forthcoming and the patient is allowed to remain in this condition long enough, the accessory muscles of respiration, particularly the sternocleidomastoids, may pull the clavicles out of the sternoclavicular joints and the patient may finally die of exhaustion.

A boy, aged 16 years, was admitted with respiratory muscle paralysis, breathing by means of the accessory muscles of respiration, chiefly the sternocleidomastoids. No respirator was available for forty-eight hours. In that time there occurred a dislocation of the sternal head of the right clavicle, evidently pulled out of place by the right sternocleidomastoid muscle.

THE EFFECT OF THE DRINKER RESPIRATOR ON RESPIRATORY PARALYSIS

Immediately after the patient is placed in the respirator, cyanosis disappears and the face assumes its natural color. The facial expression is that of satisfaction and appreciation. For the first few minutes the patient's breathing is out of rhythm with the respirator. This is indicated by the pull of the accessory muscles of respiration of the neck, by the dilatation of the alae nasi, and by the mouth being kept open, presumably swallowing air. However, the rhythm between the patient's breathing and the respirator soon becomes synchronous and the patient falls into a profound sleep, which may last for twenty-four hours or more. When he awakens, he takes fluids readily and soon learns to swallow solid food. Henceforth the patient becomes a nursing problem until such time as he is ready to be removed from the machine. In the Kingston Avenue Hospital series we treated fourteen cases of this type.

FACTS ABOUT THE RESPIRATOR

There are two facts about the respirator that should not be overlooked. They are:

1 *Negative Pressure*—When the respirator was first used all patients, regardless of age, were placed into it on 15 cm of negative water pressure, as suggested by Professor Drinker.¹ The first two patients did well. The third patient, after several days in the respirator suddenly became cyanotic, the synchronism of rhythm between the patient's breathing and the respirator was lost, the temperature rose to 103 F and the pulse to 170. Physical examination showed no evidence of cranial nerve involvement, and the patient swallowed well. The chest was resonant to percussion and auscultation revealed crepitant rales over both bases posteriorly. The sudden change in the patient's condition was therefore attributed to bilateral bronchopneumonia, proved at postmortem examination. These three patients were side by side under the same nursing care, under the same atmospheric conditions, in exactly the same type of respirator and under the same negative pressure and respiratory rate. The exciting factor causing the bronchopneumonia remained obscure. To avoid similar recurrences, all patients under 10 years of age were started at 10 cm of negative water pressure. This was increased 1 cm every three to four days to a level most comfortable to the patient, which was never

Kingston Avenue Hospital for Contagious Diseases.

1 Drinker, Philip and McKhann, C. F. The Use of a New Apparatus for the Prolonged Administration of Artificial Respiration. A Fatal Case of Poliomyelitis. J. A. M. A. 92: 1658 (May 18) 1929.

higher than 15 cm. Following this procedure, not a single patient developed bronchopneumonia while in the respirator.

2 Respiratory Rate—There are two types of the Drinker respirator commonly in use at present.² The old type has three speeds of respirations 15, 30 and 45 times a minute, the new type has respiratory rates of 15 and 30 a minute. It is important that patients requiring respiratory aid should be placed in a respirator at a rate equivalent to the normal respiration. The following incident illustrates this point.

An infant under 1 year of age died in a respirator set at 45 respirations a minute. Immediately afterward an adult, aged 18, developed respiratory muscle paralysis and was placed in the same respirator. But the physician on duty failed to move the alternator on the respirator to 15 respirations a minute. Three minutes later the patient became cyanotic, developed tonic spasms of the face and jaw muscles and went into coma. The physician opened the respirator and discovered his mistake. He moved the alternator to 15 respirations a minute, closed the respirator, and henceforth the patient did well. The phenomenon was explained on the basis of hyper-ventilation causing an alkalosis.

PROGNOSIS IN CASES OF RESPIRATORY MUSCLE PARALYSIS

The fate of a given patient placed in the respirator cannot be determined for some time in spite of the apparent improvement during the first few hours. At this stage of the disease, one cannot foretell whether the infection will be arrested below or above the bulb, or whether it will continue on to the cerebrum. The temperature and pulse rate are of no prognostic importance. The general appearance of all cases is almost identical. They may remain with pure intercostal and diaphragmatic paralysis or they may go on to (a) Landry's paralysis or (b) bulbospinal paralysis.

(a) *Landry's Paralysis*—All patients destined to develop Landry's paralysis show slight improvement for the first few hours in the respirator. These patients may then be divided into two groups. The patients in the first group become progressively worse and die within twelve to twenty-four hours, the patients in the second group linger for several days and then die. The terminal picture of the patients in the two groups is almost the same: their faces become dusky, the lips cyanotic, the eyes roll back and the eyelids remain half open. The general appearance is that of extreme anguish. The breathing is out of rhythm with the respirator, the alae nasi dilate, mucus accumulates in the mouth, and sleep lasts for ten minutes only. During this period the patients remain mentally clear. Finally they develop unilateral or bilateral facial twitchings and gradually sink into coma. The temperature rises to 105 F or higher, the pulse becomes rapid, thready and irregular, the patients vomit and finally die. There were seventeen cases in this group.

(b) *Bulbar Symptoms Superimposed on Intercostal Diaphragmatic Paralysis*—There are two groups of cases in this division that deserve special consideration. The first group comprises cases of intercostal and diaphragmatic paralysis along with bulbar symptoms, the most prominent of which is inability to swallow. The second group shows the same intercostal paralysis without disturbances in swallowing but with paralysis of some of the bulbar and cranial nerves, the com-

monest being the facial, part of the vagus, the glosso-pharyngeal and the spinal accessory.

Group 1 The patients in group 1 when placed in the respirator for the first few hours, show the improvement described. Shortly afterward bulbar nerve palsies may supervene on intercostal diaphragmatic paralysis. The signs and symptoms that these cases present depend on whether the involvement is unilateral in the bulb or bilateral. When the paralysis is unilateral, there is difficulty only in swallowing and the patients require no therapeutic aid except artificial respiration which the respirator ably supplies. These patients have an excellent chance to survive. When the paralysis in the bulb is bilateral and it is more frequently so, swallowing becomes impossible, the fluids regurgitate through the nose and saliva drools from the mouth. These cases invariably prove fatal. The patients do not die from paralysis of the respiratory center since they go on breathing in the machine long after the heart stops. The cause of death in my opinion, is paralysis of both vagal nuclei and the terminal picture suggests this explanation. The patients become drowsy, somewhat cyanotic and vomit. Tachycardia and irregularity of the heart supervene. Respirations are slow and irregular and out of rhythm with the machine and are carried on by the accessory muscles of respiration of the neck. The soft palate reflex and the oculocardiac reflex are lost.

Therapeutically, a great deal may be done for these patients but with poor results. Atropine sulphate hypodermically helps by drying up the mucus in the throat and bronchi. Repeated aspirations from the throat with the aid of a suction apparatus give wonderful relief. Gavage cannot be used in these cases, since postural drainage is of great importance. The two cannot be combined, because the fluid runs out of the stomach into the pharyngeal space and almost suffocates the patient. Intravenous dextrose can be given only with difficulty, because the patient's arm has to be removed from the respirator for this procedure. Patients usually die within twelve hours after the appearance of the bulbar symptoms. There were four cases belonging to this group.

Group 2 When patients belonging to group 2 are placed in the respirator, they show respiratory paralysis only. These patients, like those in group 1, improve instantly. Sometime later, usually on the second or third day, while the patients are still in the machine, the signs and symptoms of bulbar and cranial nerve palsy begin to appear. The commonest of the cranial nerves involved is the facial. The paralysis may not be noted for several days because the patients usually lie quiet and talk little. The easiest way to elicit evidence of facial palsy while the patients are in the machine is to ask them to show their teeth or to close their eyes. Most of these patients are very young children and for the first few days do not cooperate well. Nothing can therefore be done until they are sufficiently improved to remain out of the respirator long enough to permit examination. Some of these patients may show only a nasal twang or may be unable to pronounce the consonant *b*. Others may develop hoarseness or squeaky voices, or all these signs may be found in one patient. The patients, though they have bulbar symptoms, have no difficulty in swallowing and do well. They adapt themselves quickly to respirator life and improve slowly. I have seen only one case of this character.

² A new type of respirator is now available in which the respiratory rate may be adjusted to any number.

IMPROPER INDICATIONS FOR REMOVING PATIENTS FROM THE RESPIRATOR

At no time did we encounter any difficulty in deciding whether a patient required the respirator. The signs and symptoms calling for artificial respiration as described were very simple. The difficulty began when a decision had to be made as to whether a given patient should be removed from the respirator. In 1930, Shambaugh, Harrison and Farrell³ used the spirometer to determine the vital capacity of their 21 year old patient as a basis for removing him from the respirator, and, when his vital capacity had reached 1,950 cc and his breathing, while at rest, showed no effort, the patient was discharged. This is the accepted method of determining the ability of a patient to inhale a chestful of air, which ability normally depends on the tonus of the diaphragm and the intercostal and abdominal muscles. We therefore decided to adopt the determination of the vital capacity as a basis for removing patients from the respirator. While this method is practical with adults, it cannot be used in children, in whom cooperation is not so easily obtained. Children, at sight of the spirometer cry and, when asked to inhale a chestful of air and force it into the mouthpiece of the apparatus, close their mouths and refuse to cooperate. Wilson⁴ had similar experiences in small children. We were therefore left in the dark as to the indications for removing patients from the respirator and we were compelled to adopt the following procedure:

If a child having been in the respirator a reasonable time could stay out for eight hours without apparent respiratory discomfort, he was removed from the machine and watched for several days. If the child did not become cyanotic or perspire excessively, slept through the night, breathed without effort and was otherwise apparently comfortable, he was sent to a convalescent ward, where he remained for several weeks before being transferred to an orthopedic institution.

SUBSEQUENT HISTORY OF THESE CASES

Practically all surviving respirator cases were discharged either to orthopedic institutions or to convalescent homes.

CASE 1—A girl, aged 4 years, well developed and well nourished, who had been in the respirator for twenty eight days, was the first patient discharged. She remained under observation for several days and was then sent to a convalescent ward, where she stayed for two weeks. During this time she did not show any respiratory embarrassment, took nourishment well and was cheerful and cooperative. At the end of the two weeks she was discharged with a complete quadriplegia to an orthopedic hospital. Three weeks later, or six weeks after she was removed from the machine she was returned to the hospital for immediate respirator attention. Examination at this time did not reveal any additional neurologic changes. There was no evidence of cranial nerve palsy. The child swallowed well, the voice was clear and there were no signs of muscular atrophy. The chest and abdomen were moving freely with inspiration and expiration. The face was somewhat dusky. The respiratory rate was 35, pulse 160 and the temperature 100 F. Examination of the chest revealed no evidence of dullness but there were coarse mucous rales in the entire chest in front and behind. Inability of the patient to cough was the outstanding symptom. She was constantly attempting to clear the trachea but was unable to do so. A lumbar tap revealed clear fluid under normal pressure without any cells. Therapeutically, everything possible was done: atropine sulphate

hypodermically, oxygen inhalation, and finally the respirator as a last gesture to save her life, but without avail. She died in the respirator two days after readmission to the hospital.

CASE 2—A girl, aged 7 years, who was in the respirator thirty-five days, was watched for several days and then sent to the convalescent ward for two weeks, from which she was transferred to an orthopedic hospital. Four weeks later, or seven weeks after she was removed from the respirator, she was returned to the hospital for replacement in the machine. On admission the signs and symptoms were exactly the same as those present in case 1. The one striking symptom was her inability to cough and to clear the trachea. Every therapeutic resource was tried without success, and the child died in the respirator fifty-two hours after readmission to the hospital.

Data received from various orthopedic hospitals and convalescent homes revealed that one third of the respirator patients discharged died and that the cause of death on the hospital records was given as bronchopneumonia secondary to poliomyelitis.

The clinical picture and the physical conditions presented by these two cases did not suggest bronchopneumonia alone. Two things were definite: the bronchi and the trachea were full of mucus, and the patients were unable to cough. These are not signs of bronchopneumonia. The cause of death, as it appeared to us, was suffocation, but we lacked pathologic proof. We therefore decided to wait for an opportunity in which the lungs might be studied in conjunction with the pathologic changes in the spinal cord, for a possible explanation of the immediate cause of death.

CASE 3—A girl, aged 9 years, was admitted with a diagnosis of pre-paralytic poliomyelitis. Two days after admission, both lower extremities became paralyzed. On the third day she developed respiratory muscle paralysis and was placed in the respirator, in which she remained for twenty-one days. Following a three week period of observation, she was transferred to an orthopedic institution. One and one-half years after her first admission to our hospital she was returned to us for respirator treatment. From the history it was evident that the child developed an infection of the upper respiratory tract, the chief symptoms of which were a slightly congested throat with excessive bronchial secretions. There was no rise in temperature nor was there an elevation in the pulse rate. On the third day of her present illness she suddenly became cyanotic and dyspneic. She responded to oxygen inhalation and atropine sulphate hypodermically. She was apparently doing well for the next two days. Suddenly she once more became cyanotic and dyspneic. At this stage of her illness she was transferred to us. On admission she was somewhat anemic but alert and responsive. Her chief complaint was inability to cough up mucus which she stated was choking her. She was constantly attempting to clear the trachea but without success. Her throat was slightly congested, and the tongue was somewhat coated. The chest was resonant to percussion, and auscultation revealed coarse mucous rales in front and behind. The temperature was 100 F, the pulse was 110, regular as to rate and rhythm, and the respiratory rate was 24. The abdomen was soft and the liver and spleen were not palpable. Neurologically, she showed a complete flaccid quadriplegia with very little atrophy, the abdominal reflexes were present but sluggish, the lower intercostals and the diaphragm were apparently moving freely. It was evident from the moment the patient was admitted to the hospital that unless we removed the mucus from the trachea and the bronchi and gave the child complete chest expansion she might either drown in her own secretions or develop atelectasis. Two methods of procedure lay open before us. One was bronchoscopy with suction which we considered too drastic, the other was hypodermic treatment with atropine sulphate which we adopted along with the Drinker respirator for chest expansion. This method of treatment apparently was very effective for a short time: we soon observed that the child's breathing was out of rhythm with the respirator, her face gradually became dusky and her lips cyanotic, the temperature

⁴ Wilson J. L. Respiratory Failure in Poliomyelitis. Treatment with the Drinker Respirator. *Am. J. Dis. Child.* 43: 1433 (June) 1932.

remained at 100 F. Repeated physical and radiographic examinations of the chest did not show any signs of pneumonia. The child died in the respirator forty-eight hours after readmission to the hospital.

Permission was granted to examine at postmortem only the heart and lungs. The heart was free from pathologic changes. Both lungs were free, and detachment was easily effected. They were greatly retracted from both the diaphragmatic and the parietal pleural surfaces. In size, they corresponded to those of an infant and measured 13.5 cm. from apex to base. They were dark gray and were studded with numerous subpleural petechiae, the left upper lobe was deep purple and was firm to the touch. Dissection carried into the bronchial tree of this lobe revealed the complete occlusion of the hyparterial bronchus with a yellow plastic mucopurulent plug. Similar occlusions were noted in the bronchiolar ramifications, including the finer bronchioles of this lobe.

Microscopic examination of a section (fig 1) from the left upper lobe of the lung revealed desquamation of the ciliated epithelial cells lining the bronchioles and bronchi, which were lying free in the mucopurulent plastic exudate along with polymorphonuclear leukocytes. The basement membrane on which the epithelial cells rested was swollen. The underlying vessels were congested and the surrounding tissue was infiltrated with inflammatory cells. The cells of the mucous glands were swollen and granular. Throughout the lung the alveolar walls were relaxed and approximated, some showed evidence of catarrhal inflammation which was most marked peribronchially. The blood vessels in the alveolar walls were dilated.

PATHOLOGIC CHANGES IN THE SPINAL CORD OF POLIOMYELITIS

The clinical course of poliomyelitis may be correlated with three types of lesions in the anterior horn cells of the spinal cord: (1) an area of edema with perivascular round cell infiltration; (2) the presence of petechial hemorrhages in addition to edema and perivascular round cell infiltration; and (3) complete destruction of the anterior horn cells, along with petechial hemorrhages, edema and perivascular round cell infiltration. While it is convenient thus to describe definite areas of pathologic change in the anterior horn cells, these in fact not only merge gradually into one another but often coexist in different parts of the spinal cord. Applying these pathologic observations to the anterior horn cells of the lower motor neurons comprising the phrenic, intercostal and abdominal nerves, one can perceive that if the pathologic condition is of the edematous type the muscles innervated by these nerves will recover their function as soon as the edema subsides, performing all the physiologic processes assigned to them by nature, including coughing. A patient, therefore, suffering from respiratory muscle paralysis with an edematous type of pathologic spinal cord changes, when placed in the respirator recovers rapidly and completely, usually in the course of two or three weeks, and when removed is able to breathe and cough without difficulty.

When the pathologic changes of the anterior horn cells consist of petechial hemorrhages in addition to edema, recovery of the respiratory muscles is markedly delayed. The edematous anterior horn cells are the first to recover, and the hemorrhagic last. As soon as the edema is absorbed, impulses begin to pass down the axis cylinders to the muscle bundles. If part of the neurons that constitute the phrenic, intercostal and abdominal nerves recover, part of the diaphragm and of the intercostal and abdominal muscles regain their function. Patients suffering from partial paralysis of the respiratory muscles can and do breathe freely and without effort when out of the respirator. However, when

patients with partial respiratory muscle paralysis attempt to cough, which requires the entire function of the diaphragm and the intercostal and abdominal muscles, they are unable to do so. The average time that a patient with this type of pathologic spinal cord may have to remain in the respirator is about two months, and he may probably be able to cough by the end of six months.

Cases in which both petechiae and edema were found present in the spinal cord, showed microscopically most of the anterior horn cells intact and their nuclear staining capacity retained. Some showed the disappearance of the Nissl spindles, and loss of straining capacity in the nuclei with margination and extrusion. The gray matter was infiltrated with leukocytes and lymphocytes. Slight degenerative changes were found in the white matter, but the most obvious changes are perivascular infiltration with petechiae.

Lastly, when the pathologic changes of the anterior horn cells consist of cell destruction, hemorrhage and

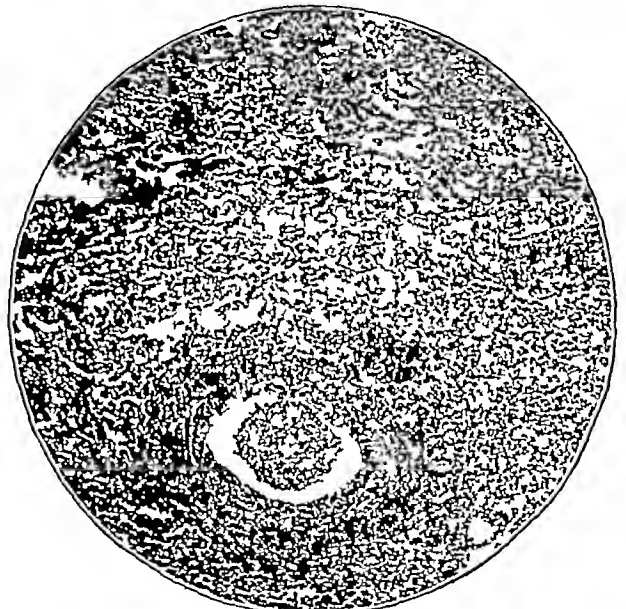

Fig 1 (case 3)—Microscopic appearance of lung

edema, recovery of respiratory muscle function may take months or years or may not occur at all, and the patient may have to spend the rest of his life in the respirator.

In health, the lungs are kept constantly expanded and their airways open. Through these tubes, they are the best drained organs in the body. The force that keeps them open is the tonus of the diaphragm and the other muscles of the thorax. When ever this tonus is lowered, as it is in the respiratory muscle paralysis of poliomyelitis, the vital capacity of the lungs is gradually diminished. In the unaerated areas, mucus accumulates until some of the airways are filled and closed. If there happens to be present also inhaled foreign material or mucus from catarrhal inflammation, these conditions also contribute to the blocking of airways. As soon as any part of a lung is thus shut off the air within it is absorbed into the blood. The occluded lung or lobe or lobules are soon collapsed, and in such collapsed areas any bacteria that happen to be present find conditions favorable for their growth and activity. This conception of the part that atelectasis plays in the development of pneumonia, first clearly stated by Coryllos and Birn-

baum⁵ is now established. It is essentially in this way that all secondary pneumonias develop.

This conception assigns to the tonus of the skeletal muscles of the body a place of prime importance in respiration. It is this tonus that keeps the lungs expanded and prevents atelectasis. The movements of respiration do not consist merely in the alternate contraction and relaxation of the thoracic muscles. In reality these muscles pass at each breath from one tonus level to another and back again.⁶ When the tonus of the entire musculature of the body is depressed, respiration is depressed also. The capacity of the thorax is greatly decreased by the relaxed and elevated diaphragm and by the flaccidity of the other respiratory muscles. In the partially deflated lungs, atelectasis readily develops, and if infection is present pneumonia results. The common sequence is lowered muscular tonus, decreased vital capacity, occlusion, atelectasis, pneumonia.

Nature apparently foresaw the possibility of bronchiolar occlusion by means of foreign bodies or mucus plugs and bestowed on the human body a mechanism

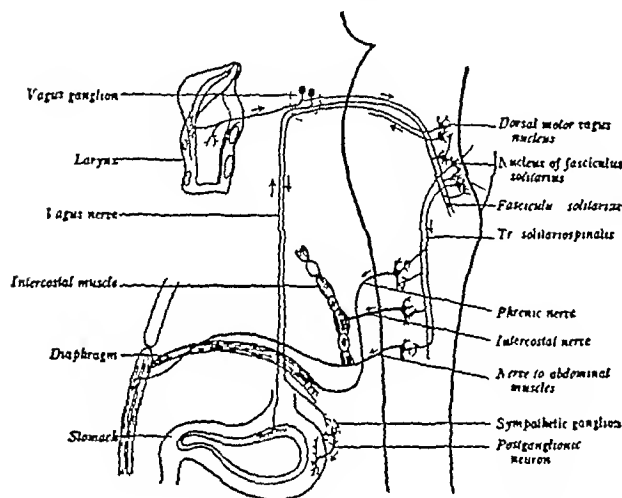

Fig 2—Mechanism of the cough reflex. From the irritated respiratory mucous membrane as for example of the larynx trachea or bronchi the disturbance is propagated along the afferent fibers of the vagus through the nucleus of the tractus solitarius and the descending fibers arising in it to the spinal primary motor neurons that innervate the diaphragm and the intercostal and abdominal muscles. (Herrick, Cajal.)

by means of which it might purge itself of these. This mechanism is the cough reflex. When the integrity of the reflex arc is broken by destruction of the anterior horn cells, coughing is impossible. Mucus slowly accumulates in the bronchioles and sets up numerous atelectatic areas. Finally, the mucus fills up the entire bronchial tree and suffocates the patient. This primarily was the cause of death in the three cases described (fig 2).

INDICATIONS FOR REMOVING PATIENTS FROM THE RESPIRATOR

Patients having been placed in the respirator remain in it undisturbed except for rotation from side to side several times daily. Whatever attention and nursing care they require are given to them through the port-holes. On the next and subsequent mornings while

getting their morning care, they are observed for ability to use their respiratory muscles. As soon as they are able to do so, they are gradually weaned from the respirator in the following manner: they are removed for one hour the first day, two hours the second day and three hours the third day, until on the eighth day they are able to stay out of the respirator for eight hours or more without apparent discomfort. These patients are then asked to cough. If they can cough they are removed from the respirator and watched carefully for cyanosis, excessive perspiration and somnolence, and in the absence of these signs they are sent to the convalescent wards. However, when they are able to breathe without effort but cannot cough, they remain in the respirator sixteen out of every twenty-four hours until such time as they are able to cough.

Improvement in muscle tonus and vital capacity is determined regularly by asking the patient to count, starting with one, two, three, until the expiratory phase of the respiratory cycle ends and the inspiratory phase begins, without using the accessory muscles of respiration. The last number counted is then noted and, as the vital capacity increases and the muscle tonus improves, the patients are able to count more numbers during the expiratory phase. By means of this simple procedure one observes that the vital capacity reaches its maximum long before the patients are able to cough.

SUMMARY AND CONCLUSIONS

1 Any case of poliomyelitis with or without a rise in temperature may develop respiratory muscle paralysis within twenty-four hours.

2 The most important indication for placing a patient in the respirator is a diminished vital capacity, which can easily be determined by the counting test, and as soon as this indication becomes apparent there is nothing to be gained by waiting for a fully established picture of respiratory muscle paralysis.

3 Ten centimeters of negative water pressure in the respirator is sufficient to start with in cases of children under 10 years of age, and the respiratory rate of the machine should correspond to the normal respiratory rate of the patient.

4 The effect of the respirator in cases of respiratory muscle paralysis is an immediate and miraculous improvement, but prognosis should be withheld for at least five days in spite of the apparent improvement.

5 The ability to breathe freely and without effort is not an indication for removing a patient from the respirator. The only indication is the ability to cough.

6 Patients removed from the respirator without being able to cough may later develop atelectasis with bronchopneumonia.

Experimental Nephritis Produced by Radium.—Chronic and renal insufficiency without hypertension has been consistently produced in dogs by intravenous injection of the active deposit of radium emanation. The length of life varied inversely with the dosage of radium. The kidneys were the only organs showing pathologic or functional change. This apparent selective action is probably due to the excretion of the active deposit of radium by the kidneys resulting in a greater concentration of radioactivity in these organs. The kidneys were uniformly small and contracted, showing glomerular tubular, interstitial and vascular changes comparable in some respects to what occurs in man in chronic hypertensive nephritis. No hypertension was produced, however. The earliest detectable change occurred thirty days after the initial dose. —Adams, Egloff and O'Hare. *Experimental Chronic Nephritis Produced by Radium*, *Arch. Path.* 15:465 (April) 1933.

THE SPECIFIC EFFECT OF "FOUADIN"
(FUADIN) ON GRANULOMA
INGUINALE

PRELIMINARY REPORT

THOMAS V WILLIAMSON, M D

WITH THE COOPERATION OF

JAMES W ANDERSON M D

RAYMOND KIMBROUGH, M D

NORFOLK, VA

AND

AUSTIN I DODSON M D

RICHMOND VA

In 1931, one of us (T V W) reported a case of bilharziasis¹ in which attention was called to the fact that a new trivalent compound of antimony and sodium, called "Fouadin," was replacing antimony and potassium tartrate in Egypt as a safer, more easily administered, and more quickly acting specific in this fluke infestation. Fouadin is named in honor of King Fouad of Egypt by reason of his enthusiastic support during its developmental stage.

There is very little news value to Americans in a story of the use of Fouadin in the infestation known as bilharziasis, or schistosomiasis, because that condition is so rare in this country. This is not true in Egypt, however, as no less than 400,000 cases of this grave, mutilating and distressing parasitic invasion were treated in the anthelmintic hospitals of the Egyptian government during the year 1928 alone. It is so well known that the intravenous administration of large doses of antimony and potassium tartrate is often accompanied by disconcerting systemic reactions, besides being difficult to administer, that one instantly appreciates the fact that the advent of a drug which obviates most of these difficulties is an event of supreme importance in the country of the Nile.

The coming of Fouadin in all probability may prove to be of great importance not only in Egypt but throughout the world, by reason of its specific effect on granuloma inguinale. Granuloma inguinale is by no means rare in the United States—indeed it is endemic here—while it is quite common in the tropics.

There are no easily available figures that show definitely the rate of occurrence of this disease anywhere. Howard Fox² says that it is much more prevalent in the United States than is generally supposed. He quotes Gage³ as saying that the reported cases do not give a fair idea of its incidence in our country. We concur heartily in this statement. Johns and Gage⁴ state that "a rough estimate of the total number of cases under treatment in the various hospitals and clinics in New Orleans would run into the hundreds." In Norfolk, our attention is being called frequently to new cases. In Dutch New Guinea, from 12 to 35 per cent of the population has been found to be infected⁵. The disease is also attracting much atten-

tion in many parts of the Orient. These statistics are sketchy and unsatisfactory, but they demonstrate conclusively that granuloma inguinale is not rare. Although it may not be alarmingly prevalent, it is grossly incapacitating when it does strike.

It must be recalled that up to the present day antimony and potassium tartrate has proved to be more universally beneficial in the treatment of granuloma inguinale than all other forms of medication. Andrews⁶ says of it "This form of treatment is thought by some to be specific, but in other hands it has proved disappointing."

While we do not mean to state that antimony and potassium tartrate is specific yet we venture to assert that it has not always been given the fullest opportunity to prove its specificity in this tropical ulceration. The reasons for this are obvious. At times, as much as 175 grains (11 Gm) of antimony and potassium tartrate must be administered to get maximum improvement. Ten cubic centimeters of a 1 per cent solution is injected intravenously at each sitting. There are approximately 2 grains (0.13 Gm) of the drug in each 10 cc of the 1 per cent solution. Thus in the neighborhood of eighty injections may be called for in an individual case. Bearing in mind the frequent unpleasant systemic reactions from intravenous antimony and potassium tartrate, and, basing our reasoning on the supposition that from fifty to eighty-five injections may be required, we ask ourselves: What, if the patient is permitted the choice in the matter, is the real likelihood that the drug has always had a fair trial to prove its ultimate potency? One should not lose track of the mental status of most of the patients who ordinarily need treatment for this curse. Treatment must be given twice each week in a continuous series, or, according to Manson the pathologic condition begins to spread again. An uninterrupted treatment period of from twenty-five to forty-two weeks is thus necessitated. Certainly, a less drastic and a shorter method of treatment would be acceptable.

Before Fouadin was introduced, antimony and potassium tartrate, therefore, was the most brilliant suppressor of both granuloma inguinale and bilharziasis.

The preliminary report of the experiment with Fouadin in bilharziasis by Professor Khalil, parasitologist of the University of Cairo, was to the effect that this new antimony compound could be injected into the muscles without deleterious local results, that depressing systemic reactions were negligible, and that the time required to obtain a cure was almost cut in half. A rough calculation reveals that this time saving is an immense advantage to the Egyptian government as it lops off some six million treatment days yearly. This estimate is based on the 400,000 cases treated in 1928. Antimony and potassium tartrate cures the disease in an average of forty days, Fouadin will produce the same results in twenty-eight days. Thus the many striking advantages of Fouadin over intravenous, more highly toxic antimony and potassium tartrate are apparent.

In the report of the cases of bilharziasis in 1931, the second case treated and reported by the author⁷ of that article, it was suggested that Fouadin might be as much superior in the treatment of granuloma inguinale as it seemed to be in that of bilharziasis. Certainly, a drug that could be injected into the muscles

Read before Norfolk County Medical Society Oct 17, 1932.
The name accepted by the Council on Pharmacy and Chemistry is spelled Fouadin.

would be better than one that had to be introduced into the veins

Shortly after the report had been published, the Winthrop Chemical Company of New York communicated with the author and informed him that the firm was the American representative of the continental makers of Fouadin. The Winthrop people expressed great interest in the suggestion of experimental work on granuloma inguinale with Fouadin and offered to import a sufficient quantity without cost for that purpose. This was done and the experiment was begun in Norfolk, early in 1932.

The originator of the experiment (T V W) whose work is confined exclusively to urogenitology, soon realized that the assistance of trained dermatologists was essential in order to obtain the most finished results. From that time on Drs Anderson and Kimbrough have been actively identified with the work. On observing the rapid and brilliant curative influence of Fouadin in the first few cases, the author became quickly convinced that a boon for granulomatous humanity had been stumbled on, and that the kindly thing to do was to secure data on enough cases to warrant an early broadcast of the method of medication. Thus, Dr Dodson happily was enlisted in the venture.

DESCRIPTION OF FOUADIN

The following excerpts are taken from the report of Prof M Khalil⁸:

Since 1924, the Bilharzia Research Section of the Public Health Department of Egypt with the cooperation of the research department of the Beyer firm has endeavored to

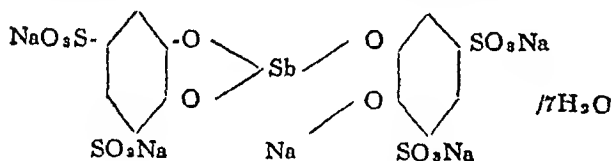

Fig 1—Structural formula of Fouadin

replace antimony and potassium tartrate with less toxic preparations such as Sb 211 and Sb 212 and Prof H Schmidt of Elberfeld has produced many preparations which were tested or modified in some cases according to experience in Egypt. Among these compounds were Stibosan 693 b now Neo Stibosan, Antimosan, Antimosan new, Antimosan new II, and Sdt. 91, which has been named in Egypt 'Fouadin'.

The formula of Fouadin (antimony-III-pyrocatechin sodium disulphonate), according to Professor Schmidt, is given in figure 1.

This preparation is used in a 7 per cent solution, in which condition it is stable and has been used after a lapse of six months in the Egyptian summer without deterioration. It is a trivalent antimony compound and is far more effective for bilharzia than the pentavalent compound of antimony. The latter is more effective in the treatment of kala-azar.

Dosage—After a series of animal experiments to determine the minimum lethal dose and its effects on the tissues at the site of the intramuscular injections it was used in man in increasing doses, the patient being kept under strict observation. As a result of treating 150 cases, the course of treatment shown in table 1 was adopted for adults.

The dose is determined for children according to their weight and not their age. Sixty kilograms of body weight is taken as the average adult weight in the scheme as shown in table 1.

The injections are given intramuscularly, preferably in the gluteal region in the two sides alternately. The drug is very easily absorbed, as shown by roentgenograms of the site of

injection, the shadow produced by the solution disappearing in nine minutes.

Observations During the Course of Treatment—No immediate effects are shown, contrary to what occurred sometimes in the case of antimony and potassium tartrate in which coughing, vomiting and fainting are noticed in a certain number of cases. During the later injections, vomiting has been recorded in a few cases, especially in patients who continued to do their ordinary work after the injections. Slowing of the pulse 10 beats per minute, occurs in a fairly large percentage

TABLE 1—Course of Treatment Adopted for Adults

Day	Dose	Fouadin 7 per Cent Solution Cc
First	First	15
Second	Second	3.5
Third	Third	5.0
Fifth	Fourth	5.0
Seventh	Fifth	5.0
Ninth	Sixth	5.0
Eleventh	Seventh	5.0

Fifteenth	Ninth	5.0
Total		40.0

of cases. Dr M Hammouda of the department of physiology, Faculty of Medicine, Cairo, and Dr Weese of Elberfeld injected the drug in very large doses into animals used for experimental work and noticed that the drug is quite safe and does not affect the vagus.

The antimony is mainly excreted by the kidneys and to a very small extent by the intestinal tract and none by the skin. The daily excretion of antimony during the whole course was determined by Dr Ali Hassan of the public health department of the Egyptian government, biochemical research department.

A comparison of Fouadin with antimony and potassium tartrate is made in table 2. In view of the facts brought out it is evident that Fouadin is preferable to antimony and potassium tartrate.

REPORT OF CASES OF GRANULOMA INGUINALE TREATED WITH FOUADIN

CASE 1—History—A Negress, aged 25 who had had a genital ulceration dating back to 1925, complained of vaginal ulceration which gave off a profuse, foul, constant discharge, and of painful incontinence of urine. The onset of the trouble was characterized by a small itching ulcer on the vulva. This

TABLE 2—Comparison of Fouadin with Antimony and Potassium Tartrate

	Antimony and Potassium Tartrate	Fouadin
Administration	Intravenous	Intramuscular
Local reaction	Inflammation, abscess or sloughing may occur	Slight or no pain
Immediate general reaction	Coughing, vomiting and fainting frequent	None
Late effect	Fever, continuous vomiting, jaundice and sudden death	In the present series vomiting only in 2.5 per cent of cases
Length of course	Four weeks	Two weeks
Expense	Very cheap	Comparatively dear
Maximum dose	2 cc maximum (44 mg Sb)	5 cc maximum (49.5 mg Sb)

spread slowly and later caused such fibrous tumefaction of the labia that a vulvectomy was done for relief. Still later the urinary function became involved to such an extent that the patient had had no control for several years. There was also a constant pain in and around the bladder outlet. The patient had had a lengthy course of treatment with neoarsphenamine and antimony and potassium tartrate before coming to us but no form of treatment had ever had a great effect on the ulceration.

⁸ Khalil, M. Nazmi, M. Peter, F. M. Salah el Din, M. and el Belash, M. H. The Treatment of Schistosomiasis with Intramuscular Injection of Fouadin. Deutsche med. Wchnschr. 58: 1125 (July) 1929.

Examination—The patient was emaciated. She had a hunted, tearful expression. This was noticed in the majority of the patients treated in this series. The Wassermann reaction was negative. There were irregular areas of granulomatous ulceration in the vagina extending as far up as the cervix and encircling the urethral outlet. Profuse, fetid discharges soaked the vulval pads, and there was the odor of uncontrolled urine.

Treatment and Result—After the third injection of Fouadin the patient complained much less of bladder pain. Following the fifth treatment, she was able to walk 1 mile to the office and maintain control of the urine. At the end of the first course of treatment, given according to the schedule of dosage of Professor Khalil which has been previously outlined, all ulceration had disappeared, the pain was gone and there was fair control of urine. The appetite was good, sleep was normal for the first time in years, and the patient was gaining rapidly in weight.

The granuloma was cured.

Figure 2 shows the cured condition. No picture was taken at the beginning of treatment because it was not thought that a good plate could be obtained. This error was not made in any of the subsequent cases, the lesions were found to photograph well. It may be noticed easily that the vaginal mucous membrane is

lacking in pigment. This cicatricial bleaching is found in most of the lesions that have been healed with Fouadin. This healing was very rapid in every case. The associated dermatologists (J. W. A. and R. K.) are inclined to believe that this bleaching, or, what is more correct, this lack of pigment, owing to the rapidity of the healing, may be permanent.

Fig 2 (case 1)—Condition after treatment with Fouadin.

CASE 2—History—A Negress aged 25, reported to us with a large perianal granuloma which had been in existence for four years. Treatment with neosarsphenamine and antimony and potassium tartrate had been given with very little result. The patient complained most of a foul smelling discharge of great amount, and of terrific nocturnal pain. This type of nocturnal pain was a symptom of many of the other cases in the series. Andrews⁹ states that granuloma inguinale is painless. We do not agree with him. Some of our patients complained bitterly of pain which, for the most part, simulated that of syphilis, in that it was most marked at night. This pain is very resistant to anodynal authority, even morphine having but partial effect on it. Nor does the phenomenon of mixed infection in the ulceration explain the symptom as satisfactorily as might be desired, there is probably some disturbance in the nerve supply involved. We found that a combination of 3 grains (0.2 Gm.) of sodium amytal with a grain each (0.065 Gm.) of codeine sulphate and extract of hyoscyamus was the most effective pain killer of the non-narcotic type of drugs. The Wassermann reaction was negative. We do not feel that the Wassermann test is of great importance in the diagnosis of granuloma inguinale, as a positive response does not rule out the disease in favor of syphilis. However we do feel that it is of great value in the subsequent check up of the patient when the granulomatous ulceration is cleared up. The question of whether the patient may have both syphilis and granuloma at one time is of considerable moment and interest.

This patient also complained of loss of appetite. This was a fairly constant observation in our cases. Loss of weight is not a constant finding, as we have seen obese persons with granuloma.

Examination—There was an enormous infected papillomatous growth extending entirely round the anus. The circumference of this neoplastic mass was irregularly oval, its radius from the anal center being 3 inches. It was elevated above the skin level throughout. Figure 3A depicts it clearly.

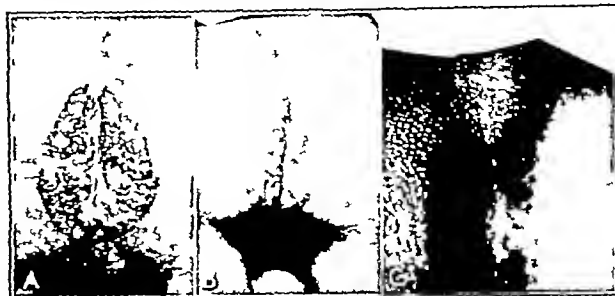

Fig 3 (case 2)—Condition A before treatment, B after ten days of routine treatment, C after ten treatments in twenty-six days.

Treatment and Result—Routine treatment every two days with Fouadin brought about the improvement shown in figure 3B in ten days. The discharge ceased after the third injection, the mass assumed a dead look and began to dry up. Following the fourth treatment there was no more pain. There was no trace of the ulcerated growth at the conclusion of the first course of Fouadin. The patient was cured in twenty-six days with ten treatments. Figure 3C shows the astonishingly perfect results.

CASE 3—History—An emaciated Negress, aged 23, had an extensive ulceration of the left groin vulva, vagina and perineum. This condition had started twenty-two months before as a pimple in the groin and spread slowly to its present dimensions. The symptoms she stressed were pain which was worse at night, large quantities of ropy, fetid discharge, and loss of appetite. From the scanty information obtained by questioning her, it seemed that she had had treatment with both antimony and potassium tartrate and arsphenamine.

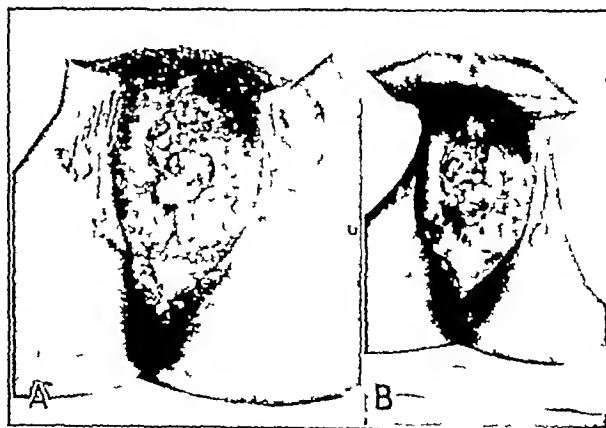

Fig 4 (case 3)—Condition A before treatment showing tabs resulting from the undermining of the labia and also the streams of secretion, B when healed.

Examination—There was a dirty ulcer in the left groin 3 inches (7.6 cm.) in length and 2 inches (5 cm.) in width. The labia, vagina and perineum presented generalized granular ulceration. The labia were so enlarged and thickened that they seemed to be the seat of elephantiasis. As the result of degenerative undermining of the labia there were several large tabs which gave the impression of pedunculated tumors. Figure 4A shows these tabs well. It also registers the streams of fetid secretion running from the lesions.

Treatment and Result—The response to treatment was very rapid. Dry crusts formed over the lesions in ten days. The removal of these crusts revealed healthy tissue beneath which possessed the hilly aspect of granulation tissue but which was covered with a definite integument. There was no black pigment in this healed area, nor has any appeared to date. There

Fig 5 (case 4) —Before treatment.

seemed to be a total lack of the formation of fibrous tissue, which seems to be a frequent sequela in the slow healing of granuloma inguinale with other forms of treatment. No tendency to fibrous contraction was observed in the rehabilitated tract.

Figure 4B tells the story of the healing. The bleached area in the left groin may be noted. The hypertrophied vulval tabs

Fig 6 (case 4) —Healing effected by treatment

remain, although they are somewhat shrunken they will be removed with the knife later.

The patient was cured in thirty days with twelve injections of Fouadin.

Special Note—This patient, together with patients 4 and 5, complained of a reaction of which no mention was made by

Professor Khalil. Beginning some ten hours after certain of the injections, there was generalized, subacute joint pain, which would persist for about fifteen hours and then subside slowly. This pain, while it was moderately severe, was never bad enough to warrant the discontinuance of treatment. When it annoyed the patient, a three day interval was allowed between the injections instead of the routine forty-eight hours.

CASE 4—History—A Negro, aged 22, had a groin and penile ulceration which had been in evidence for several years. It began as a small hard spot in the left groin and gradually spread until the greater part of the groin, penis and scrotum became involved. He was treated with antimony and potassium tartrate and with arsphenamine. The antimony and potassium tartrate healed most of the ulceration, but there always remained isolated areas that would not respond entirely. As soon as the administration of the drug was discontinued, a slow recrudescence set in. For the past six weeks the ulcerated region had been very painful.

Examination—The left groin, the left side of the scrotum and the penis in the region of the foreskin presented a number of small ulcerated areas of varying size and shape. The ulceration was shallow, was covered with dirty granules, and gave off a profuse discharge of rank odor. There was much thick fibrous tissue in the left groin which had contracted to a marked degree. The prepuce was also much enlarged by fibrous tissue. This preputial tumefaction was not lessened by treat-

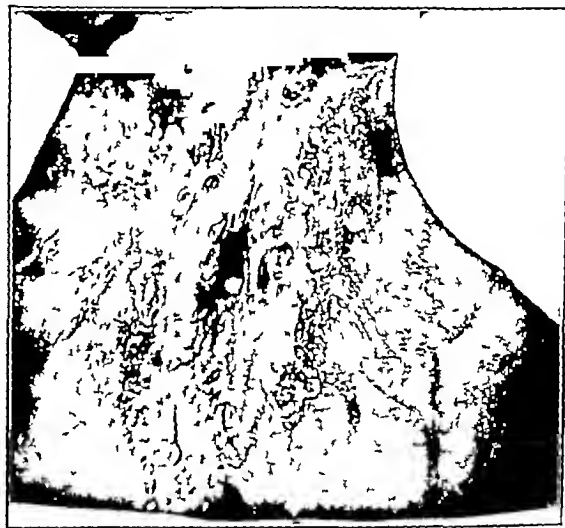

Fig 7 (case 5) —Ulceration before treatment with streams of discharge

ment with Fouadin but will be removed by cosmetic surgery later. The whole condition is depicted in figure 5.

Treatment and Result—Twelve injections of Fouadin over a period of thirty days brought about the total healing portrayed in figure 6. As the patient complained more of the joint pain reactions than any of the others, the course of injections was spread out over a longer period than usual in order to permit the disappearance of all such symptoms between injections. A total cure resulted.

CASE 5—History—A married Negress, aged 24, the mother of three small children, had been afflicted with a foul smelling, painful, extensive ulceration in the groins and perineum which had persisted for several years. The Wassermann reaction was negative. She told of having had two kinds of intravenous injections, at several times during the history of the disease, which we inferred to have been antimony and potassium tartrate and arsphenamine. Either the treatment was ineffective, or the patient was an inconsistent and irregular one. There was profuse discharge (shown well in figure 7), nocturnal pain, emaciation and loss of appetite.

Examination—An enormous ulceration involved both groins, the vulva and the perineum. It had invaded the vagina and it extended backward beyond the anus. The entire area was

badly infected, and there were several large blebs filled tightly with glairish sticky fluid. The whole pathologic condition was most repulsive. Figure 7 is more expressive than words.

Treatment and Result—A course of twelve injections of Fouadin over a period of thirty days produced the results pictured in figure 8. The lack of pigmentation may be clearly seen. There was no fibrous formation. The healed surface is smooth. Absolute cure resulted.

CASE 6—History—A young Negress of undetermined age presented herself with the following history. The time of onset was somewhat uncertain, but the condition had been in existence for at least a year. A pimple appeared on the upper portion of the right leg, it itched and was scratched, following which it spread with a fair degree of rapidity and continued to itch intensely. She went to a medical college clinic in the fall of 1931 and was given five injections of arsphenamine. The last treatment was in October, 1931.

Examination—The same general characteristics that have been noted in the foregoing cases were a part of this infection. The size of the lesions at the beginning of treatment with Fouadin June 22, 1932, was of the vulva perineum and anus anteroposterior 16 cm lateral 7.5 cm at the upper margin of the inner surface of the right leg length, 7 cm, breadth, 2.5 cm.

Figure 9 obviates the necessity for further description.

Fig 8 (case 5)—Healing without scars

Treatment and Result—After the third injection of Fouadin (5 cc.) the secretion from the granuloma had almost ceased and a scab began forming, which came off before the fifth injection. Another formed, which later came off July 4, an injection caused diarrhea, and this occurred at four consecutive treatments. July 10 injections began causing headaches, nausea and vomiting which was treated at each occurrence with the administration of camphorated tincture of opium in 2 drachm (75 cc) doses. After that, Dr. Dodson followed the Fouadin with injections of 1 cc. of 1:1000 solution of epinephrine hydrochloride. He also gave 2 drachms (75 cc.) of camphorated tincture of opium before the reactions set in.

The picture that is reproduced in figure 10 of the healed lesions was taken, August 2 forty-one days after the beginning of treatment. The same bleaching, or lack of skin pigmentation, is again noticed. This characteristic was noticed in all the cases except case 2.

Treatment with Fouadin from June 22 to Aug 1, 1932, brought about a complete cure.

CASE 7—History—A Negro, aged 36 complained of a chronic, painful penile ulcer. The onset, six months before, was characterized by an itching pimple on the shaft of the

penis near the pubic hairs. The discharge was foul smelling and profuse. During the last six weeks the ulcer had become very painful. The pain was worse at night. The patient had had "shots" for syphilis during the life of the ulcer, but no local treatment had been effective.

Fig 9 (case 6)—Before treatment

Examination—On the shaft of the penis near the right penoscrotal junction, there was an irregular, dirty, granulating ulcer, 1½ inches (3.7 cm) wide and 2 inches (5 cm) long. It gave off a foul odor and a quantity of discharge. Figure 11 A shows it well.

Fig 10 (case 6)—Result after forty-one days of treatment.

Treatment and Result—The response of this ulceration was slow at first. Three injections brought but little change in it. However, after the fifth injection, the healing was rapid and complete, with the exception of slight depigmentation, it was

difficult to locate the site of the former condition. A total cure resulted with ten injections of Fouadin. The pain disappeared after the fourth injection. There has been no recurrence in this or in any other case to date (fig 11 B).

COMMENT

We treated seven other cases in this series of experiments, but, since our picture data are not yet complete, we will not present them in detail in this already lengthy report. Suffice it to say that in no case has the

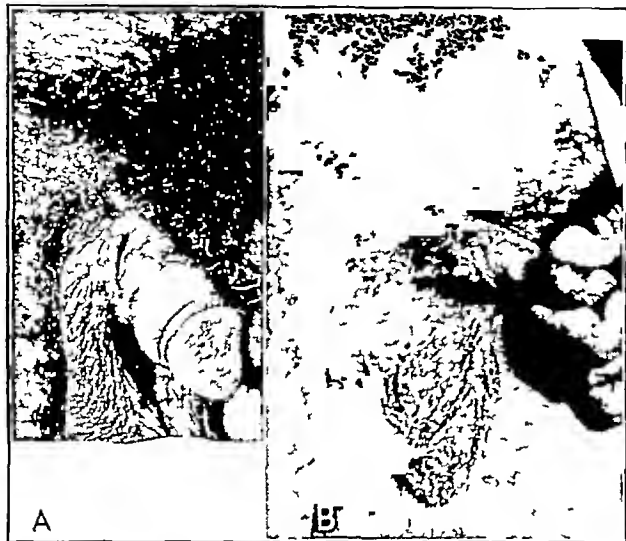

Fig 11 (case 7)—Condition A before treatment B after treatment.

treatment failed, the final result in all tallying closely with the cases reported in detail.

CONCLUSIONS

1 In treating fourteen cases of granuloma inguinale with Fouadin, we failed to notice any reaction that could be called dangerous or which revealed contraindications to its routine use in this affliction.

2 Fouadin seems to be generally superior to antimony and potassium tartrate in the treatment of this tropical ulceration.

3 Judging from our observations in this limited number of cases, we are unanimously agreed that Fouadin is a safe and rapid specific for granuloma inguinale.

EXPLANATORY NOTE

No apology is offered for presenting this preliminary report, based on the very evident paucity of clinical material, for the simple reason that we have been so favorably impressed with the behavior of Fouadin that we are not willing to keep the medical world longer in ignorance of this boon to granulomatous humanity. The desire to better the sad lot of these unfortunate ones urges haste.

It is our desire to publish an extensive report of this form of treatment later. In order that the profession may obtain a better knowledge of the amount of granuloma inguinale in the United States—or indeed, for that matter, in the world—and so that it may soon be informed of the results of extensive treatment with Fouadin, may we request all physicians both in our country and elsewhere to report their cases to Thomas V. Williamson, M.D., Suite 818, Medical Arts Building, Norfolk, Va., as soon as may be.

THE IMPORTANCE OF TUBERCULOSIS IN NATIONAL DEFENSE

E. A. MEYERDING, M.D.

Lieutenant-Colonel Medical Corps Reserve U. S. Army

ST. PAUL

Tuberculosis cost the United States government more than \$46,000,000 in 1932 for service connected compensation alone. This is only part of the bill paid annually for tuberculosis. The cost for hospitalization for tuberculosis multiplies this bill by many thousands of dollars. From 1924 to 1932 there were 61,330 veterans hospitalized for tuberculosis, occupying a sufficient number of beds to quarter two and one-fourth army divisions. In this age of pensions and the tendency to government health services, every known scientific medical procedure should be utilized to reduce the burden to the taxpayer.

Knowledge of the early diagnosis of tuberculosis has changed greatly during the past few years through the increasing efficiency of x-ray apparatus and the more practical application of the tuberculin test. The veterinarian prevents the spread of tuberculosis in herds of cattle by using the tuberculin test. It is possible to obtain approximately the same result in the human being by making use of the new medical scientific procedures. Just as typhoid has been brought under control by epidemiologic supervision, so tuberculosis may be finally conquered.

There have been several noteworthy surveys utilizing this procedure, particularly in the Lymanhurst school in Minneapolis, the University of Minnesota, Massachusetts with the ten year program, North Carolina, the University of Pennsylvania, New York City and Detroit. Results of these surveys show conclusively that it is possible to discover tuberculosis early, in fact, so early as to precede the appearance of clinical symptoms of any kind. More than 80 per cent of the tuber-

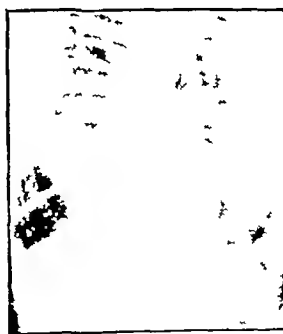

Fig 1—Appearance of chest of C. P., a man aged 24 whose father died of tuberculosis. The tuberculin test was positive on admission to the university. A roentgenogram of the chest Feb. 16, 1932, showed evidence of the first infection type of tuberculosis with the reinfection type moderately advanced involving the left upper lung field.

Fig 2—Same chest as in figure 1 April 15, 1932, showing partial collapse of left lung by artificial pneumothorax. The patient has remained ambulatory and his general health has been excellent until the present March 1933.

culosis discovered today is moderately advanced or advanced tuberculosis. With the modern intracutaneous tuberculin test and roentgen technic, this disease can be detected when there is only a minimal pathologic change.

Abstract from a thesis submitted by the author for promotion to Colonel of the Medical Corps Reserve.

The national defense forces and other government agencies are ideal groups of which to make such a survey on a large scale. The army, the navy and the national guard could incorporate into their enlistment examinations this early diagnostic procedure. Civilian groups could be tested in the R O T C, the C M T C and the reserve officers camps. The coast guard, post office department and other departments could also carry out this investigation. Not only could the tuberculin test and the roentgenogram be incorporated in the physical examination at enlistment, but also an annual examination could be given to the troops to determine the possibility of infection while in the service.

The advisability of introducing this early diagnosis of tuberculosis into the army is manifest in the annual report of the surgeon general of the army for 1932, in which he states that tuberculosis hospitalization alone costs more than \$500,000 annually.

The sum of \$400,090,176 is the total amount paid out in compensation to World War veterans for tuberculosis from 1923 to 1932. This is 33½ per cent of the total amount paid in compensation, and it does not include hospitalization. In 1932, \$46,313,184 was paid for compensation and active disability awards for tuberculosis. That is 26 per cent of the total for 1932 paid for all disabilities. Seven hundred and eighty-two emergency officers, retired for tuberculosis, were paid \$1,238,316 in 1932.

The splendid record for hygiene and sanitation of the American army during the World War is well known to all. The high standards set in 1917 encourage one to believe that tuberculosis control in the next great emergency will be comparable with that of the control of typhoid in 1917.

It is apparent that bankruptcy, or a period of stagnation, similar to what the states of the Confederacy went through after the Civil War and from which some are still suffering, has been threatening the United States. Tuberculosis plays a big part in the postwar bill, and every possible known agency that would in any way curtail this expense should be thoroughly investigated.

MODERN EARLY DIAGNOSIS OF TUBERCULOSIS

Only yesterday the diagnosis of tuberculosis required a positive sputum test, guinea-pig inoculation, or history to confirm it. Today I see many unsuspected cases of tuberculosis in apparently healthy individuals discovered through the tuberculin test and roentgenograms. Some of these were discovered extremely early, in fact, so early that with the administration of pneumothorax the patients were able to go about their daily duties without loss of time or expense to the community. Previously these cases would have gone on to

moderately advanced or advanced tuberculosis and would have required several years of sanatorium treatment. The case reported here is one of the early ambulatory types.

I have seen several young men and women at the University of Minnesota under ambulatory treatment for tuberculosis. Then, again, I have seen the robust individual with no symptoms but with extensive destruction, as the case of the football player presented here demonstrates. Discovery of this type of case can be made only by a routine tuberculin test and roentgen examination of the positive reactors. This type of tuberculous patient was undoubtedly drafted in large numbers into our national defense forces during the World War and today is placing a tremendous tax burden on the country. The case of B W, who was considered robust, is one of this type.

B W, a youth, aged 20 (fig 3), in the football season of 1931 was the crack blocking halfback for a champion college football team. At the end of the season he went in for basketball.

Early in December, he noticed that he was becoming more easily fatigued. On the advice of the coach he went to see a physician, who took a roentgenogram of his chest (fig 4).

In December, 1932, the sanatorium physician said that the disease had progressed, there had been a hemorrhage, and the young man's condition was serious.

There are apparently many young men with progressive tuberculosis who seem to be in perfect physical condition. If this young man had applied for military service in September, 1931, what chance would there have been of discovering his pathologic condition without the use of the tuberculin test and the roentgen examination?

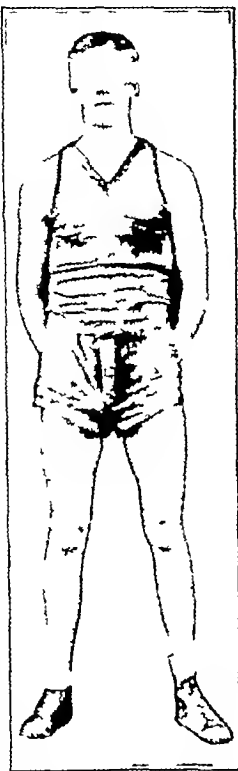

Fig 3—Appearance of B W during football season in 1931

THE INCIDENCE OF TUBERCULOSIS

The incidence of tuberculosis varies greatly. From a national standpoint, in 1925, Japan had 213 deaths per hundred thousand and France had 206. At the other extreme were the United States with 98 and New Zealand with 62. The death rate in the United States has decreased from 1900, when it was 202, to 1931, when it was 68.2. Among the states, a great variation ranges from Arizona with 291.2 and California with 90.8 to New York with 67.6 and Utah with 22.5.

Gorgas, in 1914, in his report on sanitation concerning employees on the mines on the Rand, recommended as a most important single measure "scattering."

Under normal conditions, states that are thinly populated have the lowest mortality. Contact is still the all important factor in tuberculosis.

Fig 4 (B W)—Pulmonary tuberculosis of the adult and destructive type involving approximately the upper half of the right lung. In the left lung hilus are some rather dense and irregular shadows which are believed to be due to calcium deposits representing the first infection or childhood type of tuberculosis. A slight shadow in the left first interspace near the periphery suggests a tuberculous lesion.

difficult to locate the site of the former condition. A total cure resulted with ten injections of Fouadin. The pain disappeared after the fourth injection. There has been no recurrence in this or in any other case to date (fig 11 B).

COMMENT

We treated seven other cases in this series of experiments but, since our picture data are not yet complete, we will not present them in detail in this already lengthy report. Suffice it to say that in no case has the

Tuberculosis plays a big part in the postwar bill, and every possible known agency that would in any way curtail this expense should be thoroughly investigated.

MODERN EARLY DIAGNOSIS OF TUBERCULOSIS

Only yesterday the diagnosis of tuberculosis required a positive sputum test, guinea-pig inoculation, or history to confirm it. Today I see many unsuspected cases of tuberculosis in apparently healthy individuals discovered through the tuberculin test and roentgenograms. Some of these were discovered extremely early, in fact, so early that, with the administration of pneumothorax, the patients were able to go about their daily duties without loss of time or expense to the community. Previously these cases would have gone on to

moderately advanced or advanced tuberculosis and would have required several years of sanatorium treatment. The case reported here is one of the early ambulatory types.

I have seen several young men and women at the University of Minnesota under ambulatory treatment for tuberculosis. Then, again, I have seen the robust individual with no symptoms but with extensive destruction, as the case of the football player presented here demonstrates. Discovery of this type of case can be made only by a routine tuberculin test and roentgen examination of the positive reactors. This type of tuberculous patient was undoubtedly drafted in large numbers into our national defense forces during the World War and today is placing a tremendous tax burden on the country. The case of B W, who was considered robust, is one of this type.

B W, a youth, aged 20 (fig 3), in the football season of 1931 was the crack blocking halfback for a champion college football team. At the end of the season he went in for basketball.

Early in December, he noticed that he was becoming more easily fatigued. On the advice of the coach he went to see a physician, who took a roentgenogram of his chest (fig 4).

In December, 1932, the sanatorium physician said that the disease had progressed, there had been a hemorrhage, and the young man's condition was serious.

There are apparently many young men with progressive tuberculosis who seem to be in perfect physical condition. If this young man had applied for military service in September, 1931, what chance would there have been of discovering his pathologic condition without the use of the tuberculin test and the roentgen examination?

THE INCIDENCE OF TUBERCULOSIS

The incidence of tuberculosis varies greatly. From a national standpoint, in 1925, Japan had 213 deaths per hundred thousand and France had 206. At the other extreme were the United States with 98 and New Zealand with 62. The death rate in the United States has decreased from 1900, when it was 202, to 1931, when it was 68.2. Among the states, a great variation ranges from Arizona with 291.2 and California with 90.8 to New York with 67.6 and Utah with 22.5.

Gorgas, in 1914, in his report on sanitation concerning employees on the mines on the Rand, recommended as a most important single measure "scattering."

Under normal conditions, states that are thinly populated have the lowest mortality. Contact is still the all important factor in tuberculosis.

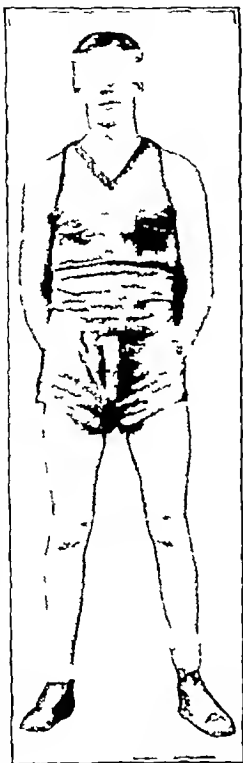

Fig 3—Appearance of B W during football season in 1931

Fig 4 (B W)—Pulmonary tuberculosis of the adult and destructive type involving approximately the upper half of the right lung. In the left lung hilus are some rather dense and irregular shadows which are believed to be due to calcium deposits representing the first infection or childhood type of tuberculosis. A slight shadow in the left first interspace near the periphery suggests a tuberculous lesion.

In Minnesota it has been found that school children, from the grades to high school, vary anywhere from 2.5 per cent positive reactors to as high as 80 per cent. There is one high school in a small town in Minnesota that had 100 per cent negative reactors. The lower percentages were in the rural districts. High schools of the large cities average about 28 per cent. In Philadelphia, one school had 72.6 per cent positive reactors and another school in the same city had 90.2 per cent. The freshmen in the universities vary, with 16 per cent positive reactors in Iowa, 33 per cent in Minnesota, 50 per cent at Leland Stanford and 59 per cent at Yale. The incidence of tuberculosis depends on environmental conditions.

CONCLUSIONS

1 There is a tuberculosis problem in national defense.

2 The utilization of the intracutaneous tuberculin test and the x-rays will screen out most of the infected individuals. The new rapid portable and inexpensive roentgen procedure used in New York City which is made by the Powers Reproduction Corporation, seems to be operating satisfactorily. More than 150 exposures can be made with ease in an hour. Paper film is used. There is a difference of opinion as to the efficacy of the paper film but I understand that experiments are being made with a translucent medium.

3 Modern roentgen examinations are practical—as to both time and cost.

4 It is not to the advantage of the individual to have a tuberculous infection.

(a) In the average case, a minimal (first, or childhood type) infection will usually resolve and heal with a calcareous deposit and resulting calcareous changes in the glands.

(b) The second infection in the average case in which there has been an early first infection as described, produces localized destruction. This may become chronic with local destruction and possible metastasis to other parts of the body. This is the most common type of tuberculosis encountered in the northern part of the United States.

(c) In the acute miliary and septicemic types of tuberculosis, one must remember that resistances are known to depend to a considerable degree on environmental factors susceptible of modification. Among these factors are inadequate or unsuitable food, industrial fatigue, physiologic stress and a low standard of living, all of which play an important part, together with faulty habits, such as alcoholic excess, in lowering resistance.

It is obvious that these factors operate only to precipitate miliary tuberculosis in a "tuberculized" population, since they do not cause tuberculosis but merely activate or aggravate existing lesions (endogenous).

A superinfection on a nonreactor, or in so-called virgin soil, together with accompanying "stress," as a rule does not permit the usual resolution of the first or childhood type of tuberculous infection. It results, instead, in a continuous pathologic condition proceeding without pause from the first into the destructive type. This superinfection causes superdestruction and brings about more rapid and more drastic complications, such as bursting of glandular tissue and emptying contents into the blood stream or bronchi, permitting miliary infections.

(d) From this one may deduce that, if one must have a tuberculous infection, it would be best to have the minimal, first or childhood type of infection early

so that when and if the second infection should occur the destruction might possibly be more gradual. I believe, however, that it is not necessary for an individual to have tuberculosis, as shown by the following figures. The entering class of the University of Iowa is only 16 per cent infected with the disease, as compared to the university class of Stanford University, California, where it is 50 per cent. Proper segregation of infected individuals (by segregation I mean the patients with early involvement placed in a quiescent or noninfectious condition and those with the more advanced type in the hospital for sanatorium treatment) will remove any inevitable contact with the disease.

(e) The veterinarians have shown that tuberculosis can be eliminated in cattle and that the herds are much better off without tuberculosis. Medical research seems to indicate that this is also true in human beings. There is good reason to believe that the rate can be cut to a negligible figure if the principles involved in the veterinarian procedure, i. e., universal testing and segregation of carriers, are applied to man. Army discipline, providing control of the individual, gives to the national defense forces an excellent opportunity to lead the way in the epidemiologic control of tuberculosis in man.

11 West Summit Avenue

FOCAL ENLARGEMENT OF THE TEMPORAL BONE AS A SIGN OF BRAIN TUMOR

SECOND REPORT

ROSS H. THOMPSON, M.D.
PHILADELPHIA

In a recent report,¹ two cases of bulging of the squamous portion of the temporal bone in young children were described by me which were due to an underlying tumor of the temporal lobe found at operation. One was the result of a meningeal fibroblastoma with cystic formation, the other, of a glomatous cyst. The latter, by displacement of the midline structures, had produced a milder degree of bulging in the opposite squama. In one case therefore, the bulging was bilateral, in the other, unilateral.

My object in this report is to record and discuss three instances of bulging of the squamous portion of the temporal bone observed in young adults aged from 23 to 28, in each of which an underlying tumor was found at operation. In two patients, evidence of organic nervous disorder was present in childhood.

REPORT OF CASES

CASE 1—*Bulging of the squamous portion of the left temporal bone directly overlying a large left temporal lobe cyst probably of glomatous origin.*

History—A man, aged 28, admitted to the service of Dr. William G. Spiller in the University of Pennsylvania Hospital Dec. 10, 1932, complained of convulsive seizures over a period of thirteen years. When he was a child 11 years of age, for no explainable reason a weakness of the right upper and lower limbs developed rather suddenly. He was able to walk, but the right-sided weakness continued over a period of two years gradually disappearing completely. During the two years the

From the Neurological Department of the University of Pennsylvania School of Medicine, and from the service of Dr. W. J. Gardner of the Cleveland Clinic, Cleveland.
1 Thompson, R. H.: Focal Enlargement of the Temporal Bone as a Sign of Brain Tumor. *J. A. M. A.* 99: 379 (July 30) 1932.

right foot dragged, but not enough to give him much annoyance. From the age of 13 to 15 years he was, as far as he knows, symptom free. At the latter age the convulsive seizures began, not accompanied by any weakness or dragging of the right toes. According to his description the attacks were of the grand mal type, frequent and often resulting in injury. There was nothing in their occurrence of localizing value and there were no definite auras. Two convulsions, witnessed by patients, were described as generalized tonic and clonic spasms with unconsciousness.

Examination—The patient was naturally left-handed, as was indicated by writing, eating, throwing a baseball and other spontaneous movements. He stated, however, that prior to the age of 7 years efforts were made to teach him right-handedness. Since the age of 7 he has used his left hand in preference to the right.

After he walked a distance of ten paces or more, the right foot showed signs of fatigue, the toes momentarily scraping on the floor with each forward movement of the foot. He was unaware of this scraping tendency and stated that he had never known weakness or clumsiness in either foot since the period between 11 and 13 years of age. Both right extremities were found to be weaker than the left, a little more than could be accounted for by the left-handedness, and there was distinct lower right facial weakness. Each of the tendon reflexes on the right side was decidedly more active than the corresponding one on the left. On the right there was a brief ankle clonus, Troemner, Rossolimo and Mendel-Bechterew phenomena, and an absence of abdominal and cremasteric reflexes. Muscular tone and synergy were normal throughout.

The squamous portion of the left temporal bone was prominent, presenting the appearance of being bulged outward. The left temporal artery was tortuous and much more conspicuous than the right.

Ophthalmologic examination showed a complete right homonymous hemianopia with preservation of central vision and a slightly enlarged blind spot in the left eye. The fundi gave no evidence of hemorrhage, exudates or choking of the disks.

Roentgen examination revealed the presence of the prominence of the left squama but no indication of increased intracranial pressure or pathologic condition of the skull. The sella turcica was normal.

Operation (by Dr Charles H Frazier)—The bone constituting the left squama was thinner than is usually encountered. A large cyst deep in the temporal lobe was evacuated, more than 75 cc. of fluid being recovered. Exploration and possible removal of the temporal lobe was considered but deemed inadvisable because of the possibility of the presence of some of the speech centers in the left temporal lobe, even though the patient was left-handed. The type of tumor was, therefore, not determined.

Examination of the bone flap by Dr Bernard J Alpers revealed no invasion of the tumor cells or any abnormality.

I am indebted to Dr W James Gardner of the Cleveland Clinic for the notes of, and permission to report, the following two cases.

CASE 2—*Bulging of the squamous portion of the left temporal bone directly overlying a large left temporal lobe cyst, less marked bulging of the squamous portion of the right temporal bone.*

History—A woman, aged 23, presented herself, Aug 25, 1932, complaining of headache, convulsions and weakness of the right extremities. It was stated that at the age of 3 years the patient had "infantile paralysis," at which time the right arm and leg were completely paralyzed for three months. Almost complete recovery occurred, apparently. However, at the age of 9 years the right limbs again became weak, so much so that she began to use the left hand in writing and had continued to do so since. For the previous two years, the weakness in the right arm and leg had been progressing more rapidly and for the past year attacks of dizziness had developed. Eight months before admission she had an attack of unconsciousness accompanied by twitching of the right side of the face and of

both right extremities. Since that time she experienced increasing headaches in the frontal and temporal regions. Three weeks and two weeks before admission similar attacks involving the right side were observed, but without loss of consciousness. During the past few months there had occurred occasional attacks of nausea and vomiting.

Examination—On examination by Dr Gardner, the patient presented a definite paresis of the right extremities and of the right lower part of the face. There was also a slight impairment of pain and tactile perception over the right side, including the face. The corneal, pharyngeal, palatal and abdominal reflexes were diminished on the right side. The biceps, triceps, patellar and achilles reflexes were exaggerated on the right side, and there was a positive Babinski sign when the right sole was stroked. There was no astereognosis, apraxia or diminution of deep sensation. On account of the pronounced weakness, it was not possible to test for synergy on the right side.

Fig 1 (case 1)—Bulging of the squamous portion of the left temporal bone directly overlying a large left temporal lobe cyst.

Examination of the skull revealed a swelling of the squamous portion of each temporal bone, particularly marked in the left. The swellings were not tender and were stated by Dr Gardner to have been more pronounced than figure 2 would lead one to believe. (The photograph was obtained with some difficulty after the patient had been anesthetized with tribrom-ethanol.)

Ophthalmologic examination revealed a low grade edema of both optic disks which was not measurable. Visual acuity was 6/75 in the right and 6/6 in the left eye. Visual fields were full, both for form and color. There was no displacement of the globes.

Roentgen examination showed a large calcified tumor in the left temporoparietal region.

Laboratory examination disclosed nothing significant.

Operation (by Dr W James Gardner)—A large section of bone was removed from the left temporoparietal region, August 26. In the center of the exposed cortex was a widened, flattened gyrus and a large venous channel. A brain cannula introduced through this gyrus encountered a large quantity of

syrupe, yellow fluid. The cyst, about the size of an orange, extended to the falx, anteriorly beyond the fissure of Rolando, posteriorly to the occipital lobe and downward into the temporal lobe. At several points there were calcifications in the cyst wall. The wall was covered with cholesterol crystals which imparted to it a silvery appearance not unlike a freshly painted radiator. The gross diagnosis was cholesteatomatous cyst. It appeared likely that a complete removal of the lesion would necessitate considerable cerebral damage, which would

Fig. 2 (case 2)—Bulging of the squamous portion of the left temporal bone directly overlying a left temporal lobe cyst; less marked bulging of the right temporal bone.

result in a permanent hemiparesis and, if the speech center was located in this hemisphere a serious degree of aphasia. It was decided, therefore, not to attempt a complete removal at the time. Approximately one third of the lining membrane of the cyst was, therefore, removed by blunt dissection, following which the remaining cavity was irrigated by saline solution, the dura closed closely, the section of bone replaced and the wound closed.

Microscopic examination of the bone flap was not made. Aside from the bulging, the macroscopic appearance was in all respects normal.

The pathologic diagnosis was gliomatous cyst.

CASE 3—Fulness of the squamous portion of the left temporal bone and enlargement on the left side of the frontal bone, mandible and probably also of the zygoma and maxilla with a fibroblastoma situated on the left lesser wing of the sphenoid bone.

History—A man aged 23, came to Dr. Gardner at the Cleveland Clinic July 7, 1932, complaining of headache, dizziness and blurring of vision. He had been perfectly well until April 1932, when he was injured in a baseball game, striking the right occipital region and being rendered unconscious for about five minutes. His symptoms developed on the following day and continued unchanged.

He had had facial asymmetry; his mother stated all his life the left side of the face appearing larger.

Examination—There was tenderness in the left temporal region and hypertrophy of the bones of the left side of the face (the frontal, zygoma, maxilla and mandible) together with a fulness of the left temporal region. The sense of smell was somewhat impaired on the left side. The right patellar reflex was absent, the left, hypo-active. On questioning the patient stated that he had some tremor of the right leg after the accident.

Visual acuity was 6/6 in each eye. The fields showed a right-sided notching in the horizontal line, possibly indicative of a partial right homonymous hemianopia. Choking of each disk was present to between 2 and 3 diopters.

Cerebrospinal fluid examination showed that the pressure was 500 mm. of water and the fluid slightly xanthochromic.

Roentgen examination disclosed a line in the right parietal region suggestive of fracture, an indistinct calcification in the left frontal region, and slight erosion of the posterior clinoid processes.

Clinical diagnosis appeared to lie between a subdural hematoma and a left frontal lobe tumor. Dr. Gardner decided to make a bilateral trephining and, if a subdural hematoma was not encountered, to perform a ventriculogram. As no hematoma was detected an attempt was made to inject air into the ventricles. As neither ventricle was met, an encephalogram was decided on, although the bone hypertrophy of the left side of the face, the fulness of the left temporal region and a suspicious shadow in the roentgenogram suggested that the lesion was in the left frontotemporal region.

The resulting film disclosed no air within the cranial cavity, excepting a small amount above the corpus callosum, which was displaced to the right, indicating an expanding lesion of the left cerebral hemisphere. The cisterna magna was well outlined, signifying that a cerebellar hernia was not present.

Operation (by Dr. Gardner)—A left frontotemporal craniotomy was performed and the bone found to be very porous and hemorrhagic throughout almost the entire exposure. A meningeal fibroblastoma was discovered arising from the lesser wing of the sphenoid bone on the left side.

The bone immediately overlying the tumor was rather thick, was quite soft and bled freely. Microscopic examination of a

Fig. 3 (case 3)—Fulness of the squamous portion of the left temporal bone and enlargement of the bones of the left side of the face with a fibroblastoma situated on the left lesser wing of the sphenoid bone.

specimen from the left frontal and one from the left temporal portion of the flap showed cancellous bone, but no tumor cells could be demonstrated.

The specimen consisted of a tumor mass in several fragments weighing 25 Gm. It was purplish red, soft and spongy in character and extremely friable.

The microscopic diagnosis was fibroblastoma.

Examination of the dura (two specimens taken from the immediate overlying region) showed thickening and the pres-

ence of small nodular projections on the surface, varying in size up to 3 mm in diameter. Microscopically one specimen showed masses of tumor cells in a localizing plaque on the surface, the other showed no evidence of tumor cells.

COMMENT

The most important feature to be considered in the presentation of these three cases is the discovery in adult life of bulging of the squamous portion of the temporal bone directly overlying a brain tumor. How long the prominences had been present before discovery is not known but there is evidence that they probably occurred in childhood. Indeed, if the compensatory dilatation of the skull is to receive a satisfactory explanation commensurate with present knowledge of the normal development of the brain and braincase it is essential that the onset of the tumors be placed in early life.

In man, the skull is an osseous box having developed from a membranous and a cartilaginous embryonic state. The sides and the convexity of the vault are originally membranous, and the skull base and the facial skeleton, originally cartilaginous. Later, nests of bone areas or points of ossification appear in both membranous and cartilaginous structures. At the time the development of the cartilaginous base of the skull begins, the brain is already developed and shaped to some extent.

The ideas of the relation of the development of the skull to growth of the brain have within late years undergone change. Not so long ago it was held that microcephalic idiocy was caused by the failure of the skull to expand sufficiently to permit normal cerebral development. Lannelongue's operation of linear craniotomy was devised and performed to overcome the effect of premature suture closure. Spiller,² in 1898 carefully considered the advisability of this operation and his paper contained the views of W. W. Keen from a personal experience covering eighteen cases. It is now generally recognized that growth of the brain is the principal factor that influences suture closure and also the size and shape of the cranium. Dabelow³ described how the curvature of the brain at the time of the development of the cartilaginous base of the skull was the determining factor for the type of curvature of the base of the skull. He related how the parts of the skull had to adjust themselves to the brain, forming like a cast about it, imitating the conformation of the brain.

Bolk⁴ stated that the different bones of the skull cannot unite before the brain has attained its final volume. According to him, the physiologic function of the sutures is to produce new bony tissue along the margins of the skull bones for the sake of the enlarging braincase. Their function he explained, is continued as long as the braincase needs enlarging, i. e. as long as the brain increases in volume. Schüller⁵ stated that the growth of the skull and its final size depended in the first place on the size of its contents. If the brain is backward in its development, the skull is in most cases smaller. On the other hand, he continued an abnormal enlargement of the skull contents always

causes an excessive dilatation of the skull, provided the enlargement of the contents occurs at a time when the skull can still change its size.

Just how long the braincase remains plastic and amenable to enlargement and molding by the development of an abnormal intracranial content such as an encroaching tumor, is a question. Merkel⁶ was of the opinion that the skull enlarges normally under the stimulus of the growth of the brain up to the seventh year. "At puberty," he stated, the maximum thickness is usually attained and at 20 growth in thickness is completed. He noted, however, that individual variations are common both in bony development and in closure of the sutures. In some, the sutures close early, in others, they remain open for many years beyond the average.

Loeschcke and Weinnoldt⁷ cited Thoma to the effect that the marginal appositional growth of the sutures is completed in the third year of life and that after this period only interstitial growth occurs. They believed these age limits to be too early. In their complete series of patients under 20 years of age they found the appositional marginal growth still incomplete. Between the twentieth and thirtieth years, they stated, the skull and brain come to the end of their growth but there are wide individual variations so that in some persons these limits may be lower or higher.

In these quotations I think lies the essence of the explanation of the occurrence of the bulging of the squamous portion of the temporal bone in these three young adults. The only obvious explanation is that in each the tumor was present for a considerable time and exerted direct pressure on the braincase in its naturally weakest part at a time when it was still plastic. An early occurrence permitted the tumor to take advantage of the resources of the skullcase to be molded by the added pathologic mass because of its inherent elasticity. Consequent added intracranial capacity could permit the necessary decompression to remove or modify the symptoms existing at the time before the bulging occurred.

In case 1 the paresis of the right extremities developing at the age of 11 years may or may not have been indicative of a lesion of the left cerebrum. Also, the disappearance of the weakness after a period of two years may or may not have been an indication of decompression of the growth by the giving way of the left squama. The patient stated that he was never aware of hemianopia; never had weakness of the right extremities after the age of 13 years or of the right lower part of the face at any time and never recognized any degree of asymmetry in his skull. Nevertheless he had, on admission, a right hemiparesis, a right homonymous hemianopia and a bulging of the left squama. His only complaint was the grand mal seizures. Snapshots taken at the age of 18 years show that the prominence in the left temporal region was just about as apparent then as now. It would appear, therefore, that the first symptoms of tumor of the left temporal lobe began at the age of 11 years, and that weakness of the right side gradually lessened in intensity within two years and then remained distinctly lessened to such a degree that he did not recognize it. The lack of knowledge of inability to see to the right highly valuable in confirming the diagnosis might sug-

gest so gradual an onset that plenty of time was afforded for its compensation. It is known that hemianopic patients do not always recognize their hemianopia.

In case 2 the sequence of events is much the same. The first appearance of weakness occurred in the right limbs at 3 years of age. Here, again, a more or less complete recovery ensued, but it was followed by a relapse at 9 years of age. The bulging of the opposite squama no doubt was caused by the shifting of the lateral ventricles and midline structures to the right, exerting direct pressure there.

It is interesting to note that complete hemiplegia and complete aphasia followed the removal of one third of the tumor wall of the cyst in a right-handed person. Both subsided satisfactorily, however, but not completely, and no further convulsions have occurred over a period of five months.

In case 3 in addition to the bulging of the left squama, there existed a hyperostosis of the left side of the face which the young man's mother stated had been present throughout life. The bulging is indicative of direct intracranial tumor pressure, as in the previous cases. But what explanation may be offered for the enlargement of the bones of the face? Cranial enlargement overlying meningeal fibroblastoma has received much recent study, but enlargement of the bones of the face in the immediate vicinity of a meningeal growth has not projected itself as far as is known into the literature. There does not seem to be, however, any reason why it might not occur.

Winkelman⁸ found bony thickening and some tumor infiltration of the orbital roof in association with an overlying basal meningeal fibroblastoma. He referred to Spiller's⁹ quotation of Pancoast, that the latter has seen roentgen evidence of increased density and thickening of bone in association with meningeal tumors of the base. List¹⁰ cited Mayer, who found by roentgen examination hyperostosis of the petron in angle tumor without going into the nature of the histologic diagnosis. The base of the skull and the bones of the face, after all, have much in common with the bones of the vault in origin, structure and function. The facial bones do not contribute to the braincase but become differentiated to accommodate and protect the organs of the special sense and the upper part of the digestive path. Whatever may be the mechanism responsible for the bony morphogenesis, it would appear that its location is determined by the site of the tumor.

If the statement is true that the facial enlargement was present throughout life, what is its connection with the fibroblastoma? If the tumor produced a facial enlargement, it must have been present in extremely early life.

SUMMARY

1 Three instances of focal bulging of the squamous portion of the temporal bone, due to an underlying brain tumor, were discovered in adults, aged from 23 to 28, and afforded valuable information for diagnosis and operation.

2 In two cases, the bulgings probably occurred in childhood.

9 Spiller W G. Hyperostosis Associated with Underlying Meningeal Fibroblastoma. *Arch. Neurol & Psychiat.* 21: 637 (March) 1929.

10 List Carl. Die Differentialdiagnose der Kleinhirnbrückenwinkel Erkrankungen mit besonderer Berücksichtigung der Tumoren. *Zschr. f. d. ges. Neurol u. Psychiat.* 144: 73 1933.

3 Two cases were due to large glomatous cysts, one, to a meningeal fibroblastoma.

4 Two cases were unilateral, the other was bilateral, producing a milder bulging of the opposite squama.

5 The meningeal fibroblastoma, arising from the lesser wing of the left sphenoid bone, in addition to the bulging of the left squama, was associated with hyperostosis of the bones of the corresponding side of the face.

6 There is an influence of the growth of the brain on suture closure and on the size and shape of the braincase.

7 The size and shape of the young plastic skull is especially influenced by direct pressure from an encroaching intracranial tumor in the region of the squama.

8 The question arises as to whether or not a fibroblastoma of the base of the brain in the vicinity of the lesser wing of the sphenoid bone can produce hyperostosis of the facial bones of the ipsilateral side.

THE USE OF THORIUM DIOXIDE IN THE DIAGNOSIS OF LIVER ABSCESS

ROBERT J REEVES, MD

AND

ELBERT D APPLE, MD

DURHAM, N. C.

During the last three years, numerous articles have appeared in the literature on the use of colloidal thorium dioxide in roentgenologic diagnosis. Most of this work has been experimental and, because of the questionable sequelae, it has not been widely used in clinical diagnosis. The Council on Pharmacy and Chemistry of the American Medical Association¹ recently gave a comprehensive report on the general use of the drug, it considered it still in the experimental stage.

According to available literature, thorium dioxide was first used clinically by Radt². Since that time, many reports concerning its use in small series of cases have been recorded.

Stewart, Einhorn and Illick³ have used thorium in the diagnosis of patients with varied clinical complications.

McDonald⁴ used the drug as an aid in the clinical diagnosis in eighteen patients. At the time of his report, none of these cases had come to autopsy.

Menville⁵ gives probably the most comprehensive report in the use of thorium dioxide in visualization of the lymphatic system.

DISTRIBUTION OF THORIUM IN TISSUES

Thorium dioxide possesses the property of depositing itself throughout the cells of the reticulo-endothelial system. The liver, spleen, bone marrow and lymphatic glands receive relatively the same amounts. Smaller

amounts have been found in the suprarenals, the ovary and the kidneys

Radt made histologic studies of the liver and spleen, one year and nine months after injecting thorium in mice. He was unable to find any pathologic changes. His conclusions were that it was a safe procedure and that the drug was nontoxic.

Shute and Davis⁶ were impressed, however, by the widespread degeneration found in the liver and spleen. The dosage of Thorotrast used by them was considerably larger than is necessary to visualize these organs on the roentgenogram. These observations correspond with our results in which large doses of from 0.5 to 2 cc. were given intravenously to small white mice. Smaller doses, from 0.05 to 0.1 cc., were well tolerated, without evidence of degenerative changes. Kadrnka⁷ suggested the possibility of therapeutic effects, as he had two cases with advanced carcinoma which were considerably improved for a time. It has been hoped that by subcutaneous injection the lymphatics will take up the thorium and some of it will be secreted into tumor tissue, thereby producing more absorption of radiant energy. Menville⁸ found that the lymphatic system did not take up thorium on intravenous injection. Small amounts of thorium were injected into the tissues surrounding blood vessels. Roentgenograms taken later showed the lymph nodes clearly visualized.

INHERENT DANGERS IN THE USE OF THORIUM DIOXIDE

The question of radioactivity of thorium dioxide is discussed fully by the Council on Pharmacy and Chemistry,¹ and insufficient time has elapsed to determine, because of the imperfect elimination, whether or not a partial conversion to mesothorium and radiothorium will occur.

There is practically no reaction when the substance escapes into the tissues about the vein.⁵ Dickson⁸ has attempted various methods of injection of thorium but has been unable to find definite harmful results. The questionable point remains that of ultimate toxicity.

As the majority of reports in the literature are chiefly concerned with the

Fig 1—Markedly enlarged liver and cavity measuring 14 cm. in diameter situated in the posterior aspect.

detection of hepatic metastases, other conditions are given in which the intravenous use of thorium dioxide is of value, but no case reports have been cited.

REPORT OF CASE

B. D., a white man aged 50, a farmer, was admitted to the medical service of Duke Hospital, Nov. 21, 1932, complaining of pain in the right upper part of the abdomen of seven weeks' duration, accompanied by a mild diarrhea.

The patient had been well until the last five years, during which time he had had intermittent attacks of diarrhea coming on every two or three months and lasting about two days. At various times during this period, blood had been noticed in the stool. Seven weeks prior to admission, he was forced to quit work because of a severe, sharp penetrating pain under the right lower costal margin. The pain was continuous and could not be relieved by sedatives. There was no nausea or vomiting. Four weeks before admission, his temperature became elevated for four days. Following this there was an intermittent diarrhea with as many as twelve stools a day. They were watery in character and at times contained mucus and blood.

Fig 2—After aspiration of the cavity.

Physical examination was essentially negative except for the large mass filling the right upper part of the abdomen and extending down into the flank, four finger-breadths below the costal margin. Examination of the blood was essentially negative except for a mild secondary anemia. Examination of the stool disclosed gross blood which was watery in character. *Amoeba histolytica* was disclosed by microscopic examination, which showed numerous motile organisms.

Emetine hydrochloride in 1 cc. doses was begun, December 18. Thorium dioxide was given in 12 cc. doses with a total dosage of 72 cc. over a period of fourteen days. Roentgen examination of the abdomen three days after the last injection disclosed a markedly enlarged liver and a large rounded area of diminished density situated in the posterior portion of the liver, measuring 14 cm. in diameter.

Jan. 7, 1933, the abscess was aspirated and about 300 cc. of muddy pus was obtained. No amebas were found on microscopic examination.

January 14, the patient was discharged with instructions to return for further treatment. The roentgen examination showed that the abscess cavity was about half its former size.

Rapid Typing of Pneumococci—A rapid typing for pneumococci that would avoid the present clinical delay is currently reported by Drs. R. H. Sia and S. F. Chung (*Proc. Soc. Exper. Biol. & Med.* 29: 792 [April] 1932) of the Peiping Union Medical College. The Sia technic consists in plating the clinical material on type-specific antiserum-agar, that is, on dextrose-agar plus from 1 to 5 per cent of type-specific anti-pneumococcus rabbit serum. The homologous type pneumococcus colonies growing in the depths of this medium show annular opacities or local precipitin reactions surrounding each colony. The development of these annular opacities is allegedly strictly type specific.

Clinical Notes, Suggestions and New Instruments

PRIMARY CARCINOMA OF LIVER WITH SPONTANEOUS RUPTURE

WILLIAM H. MAST, M.D. AND CHARLES W. STREAMER, M.D.
PUEBLO, COLO.

Review of this case is undertaken because of the infrequent occurrence of spontaneous rupture of a primary carcinoma of the liver, simulating an acute surgical condition of the abdomen.

A white man, aged 34, was admitted to the hospital Oct. 12, 1932 with a diagnosis of ruptured peptic ulcer, made by a physician in a neighboring town. The family history revealed the fact that a maternal grandfather and one brother were supposed to have had congenital syphilis. The past history was negative for serious illness, operations or injuries.

About six years before, the patient had consulted a physician because of gas and constipation. At that time he was told that he had "liver and heart trouble." He was given medicine which relieved him so much that he was able to resume his work on the farm. During the past six years he had been fairly comfortable, although he had suffered from flatulence and constipation almost constantly. He had noticed a gradual loss of weight—about 25 pounds (11.3 Kg.) during the past two years. He had never experienced any abdominal pain.

Sept. 10, 1932 the patient drove a tractor, as usual. Next day he had a sudden lancinating pain in the right upper part of the abdomen which was not referred. He was nauseated but did not vomit. He was in mild shock when the family physician was called and with a history of gastro-intestinal disturbance and muscular rigidity of the right upper part of the abdomen, a diagnosis of ruptured peptic ulcer was made.

The temperature on admission was normal, the pulse 130 and very weak. On physical examination the patient was conscious, cooperative, in mild shock and acutely ill. He appeared very anemic and there was a slight icteric tinge of the skin. The face and trunk were covered with many raised tumors, varying in size from a pea to a walnut, some with sessile and others with pedunculated bases. (Similar tumors were present on one brother, the mother and a maternal grandfather and were typical of fibroma molluscum, or Recklinghausen's disease.)

There were a few patches of bronchopneumonia in the right base. The cardiac dullness extended 1 cm. to the left of the midclavicular line. The point of maximum intensity was in the fifth interspace and the heart sounds were of poor quality. There was a loud systolic murmur at the apex and the mid-sternum transmitted toward the left axilla. There was moderate rigidity of the muscles in the right upper abdominal quadrant. The rest of the abdomen was quite distended and voluntary rigidity was present. There was a definite mass palpable in the upper quadrant which extended 13 cm. below the costal margin and 12 cm. to the left of the midsternal line. It was not particularly tender and moved with respiration. The prostate was of normal size and consistency. Bones, joints and reflexes were normal. There was no adenopathy.

The white count was 13,700 with 86 per cent polymorphonuclear cells, 12 per cent of which were immature forms. The hemoglobin was 65 per cent and the erythrocytes numbered 3,120,000. The urine showed two plus albumin and many hyaline and coarsely granular casts. The Wassermann test was not done. A flat plate of the abdomen was negative for free gas under the diaphragm.

Symptomatic treatment was given along with digitalis in large doses. The condition of the patient rapidly grew worse. The pulse ranged between 130 and 170, the temperature rose from normal to 106 and the respirations were increased in proportion. The pneumonia extended and he spit up large quantities of tenacious, purulent sputum. There was occasional vomiting but never any hematemesis. The white count increased to 33,600. The patient became delirious just before death and died on the fourth day. A meningismus developed just before death with marked orthotonus. The Kernig sign was positive, the abdominal reflexes were absent, the knee jerks were diminished, and the Babinski sign was positive bilaterally.

The autopsy revealed an extensive bronchopneumonia of the right base. The heart was slightly enlarged in all diameters

and there were calcareous deposits and narrowing of the orifice of the mitral valve. About 1,500 cc. of hemolyzed blood was found in the abdominal cavity. The liver filled the entire upper part of the abdomen. It was grayish white and the surface was covered with nodules varying in size from a pea to a walnut. At the lower anterior surface of the right lobe there was a deep rent in the capsule and liver substance, about 3.5 cm. long, which apparently accounted for the free blood present. The liver was very friable, the pressure of the fingers on the organ during removal being sufficient to tear it. The weight was 3,360 Gm. (7 pounds). A large circumscribed tumor in the center measured 12 by 10 cm., and numerous smaller ones were seen throughout the substance of the liver.

The gallbladder and ducts were normal in every respect. The stomach, intestine, kidney, bladder and prostate were normal. There was definite adenopathy of the mesenteric glands of the colon and upper part of the jejunum. Both kidneys showed evidence of chronic nephritis.

The microscopic examination of the liver revealed a primary carcinoma of the multiple nodular variety, the nuclei and general structure of the cells giving definite evidence of origin from the liver tissue. The mesenteric glands showed only fibrosis and lymphocytic infiltration.

SUMMARY

A man, aged 34, with a history of chronic indigestion, was suddenly taken ill while at work, with symptoms simulating an acute surgical condition of the abdomen. The patient was not operated on and rapidly became worse, dying within four days. Necropsy revealed a primary carcinoma of the liver, which had ruptured spontaneously, filling the abdomen with 1½ quarts of dark blood.

COMMENT

This case is presented because of the unusual occurrence of spontaneous rupture of primary carcinoma of the liver with symptoms of an acute condition of the abdomen.

It is interesting to conjecture that there may have been a tendency to tumor growth, owing to the presence of fibroma molluscum over the trunk and face. A diagnosis of ruptured peptic ulcer was easily ruled out after the initial involuntary rigidity disappeared and the liver became palpable. Later, the diagnosis of chronic passive congestion of the liver or some new growth in this organ was considered. The fact that the patient had been working hard for a number of years with no symptoms of cardiac decompensation would tend to rule out the former. We were unable to account for the abdominal symptoms until necropsy was performed. It seems quite plausible that the jar from the tractor which the patient was driving was sufficient to cause the rupture found in the liver.

UREA CRYSTALS IN CANCER

WILLIAM M. MILLAR, M.D., CINCINNATI

The peculiarly penetrating fetor of a sloughing cancer is one of the horrible aspects of this disease. For the past year at the Tumor Clinic of the Cincinnati General Hospital, urea crystals¹ have been advocated and prescribed in such cases. If they are packed into the wound the odor will be stopped to a great extent. Although they dissolve in a few minutes, the offensive character of the ulcer becomes less with each application. The crystals are cheap; they possess a considerable antiseptic value, and there is no fear of a systemic reaction. The danger of burning the surrounding skin which is considerable when the average dispensary patient attempts to use surgical solution of chlorinated soda at home, is avoided. There is one objection. After several days treatment an occasional patient will complain of pain in the wound after packing. This can readily be relieved by morphine or other narcotics, a therapeutic measure which is not as drastic as it sounds, for by this time the terminal stage has been reached in the greater proportion of cases and the patients have been taking opiates for the relief of the pain of the cancer itself. This being the case there is no reason why the strength or frequency of the narcotic cannot be adequately increased.

From the Department of Surgery, College of Medicine of the University of Cincinnati.

¹ Suggested by Dr. John Foulger of the Department of Pharmacology, University of Cincinnati College of Medicine.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary

DEXTROSE (See New and Nonofficial Remedies, 1933, p 267)

The following dosage form has been accepted

Dextrose Ringer's Stock Solution Five Times Concentrated Abbott. A solution containing 25 per cent by weight of dextrose U S P (equivalent to 28.1 Gm. $C_6H_{12}O_6 \cdot H_2O$ in 100 cc.) in concentrated Ringer's solution (five times strength). When one volume is diluted with water to exactly five volumes the resulting solution contains 5 per cent by weight of dextrose U S P (equivalent to 56 Gm. $C_6H_{12}O_6 \cdot H_2O$ in 1000 cc.) in a Ringer's solution containing in 1000 cc. of aqueous solution sodium chloride 7.0 Gm. potassium chloride 0.3 Gm. anhydrous calcium chloride 0.25 Gm. The product is marketed in ampules of 100 cc.

Actions and Uses—This product (after dilution with four volumes of freshly distilled water which provides a somewhat hypertonic solution) is proposed for continuous venoclysis over prolonged periods. It is intended as a source of dextrose for the maintenance of nutrition and of ions in balanced ratio for the maintenance of the salt equilibrium of the blood stream.

Dosage—According to the needs of the individual case. Generally 500 cc. per hour may be administered until the blood pressure is satisfactory. The flow is then diminished to 100 cc. per hour which may be continued for several days if necessary. When given for shock in the absence of low blood pressure the rate of flow should not exceed 200 cc. per hour at any time.

Prepared by the Abbott Laboratories North Chicago, Ill. No U S patent or trademark.

Dextrose Ringer's stock solution five times concentrated Abbott occurs as a clear colorless solution possessing a slightly saline taste. The specific gravity is from 1.128 to 1.120 at 20 C.

Add a few drops of the solution to 5 cc. of hot alkaline cupric tartrate test solution. A copious red precipitate of cuprous oxide is formed. Dilute 3 cc. of solution to 10 cc. and add one drop of iodine solution. The liquid is colored yellow (soluble starch negative). 2 cc. of the solution diluted to 10 cc. conforms to the U S P χ test for heavy metals. 5 cc. of the solution conforms to the U S P χ test for arsenic.

To 4 cc. of Dextrose Ringer's stock solution five times concentrated Abbott in a suitable test tube add sufficient water to make 9 cc. of solution. Add 1 cc. of freshly prepared sodium cobaltic nitrite solution and mix thoroughly. Similarly treat in exactly similar test tubes portions of a standard aqueous solution containing 1.5 Gm. of potassium chloride (previously dried) in 1000 cc. the turbidity produced by 4 cc. of Dextrose Ringer's stock solution five times concentrated Abbott at the end of ten minutes is less than that produced by 5 cc. and greater than that produced by 4 cc. of the standard solution (limit of potassium $[K^{++}]$).

Transfer 1 cc. of Dextrose Ringer's stock solution five times concentrated Abbott to a Nessler tube. Add 0.5 cc. of diluted acetic acid, 40 cc. of water and 5 cc. of ammonium oxalate solution. Dilute at once to 50 cc. and mix thoroughly. Similarly treat portions of a standard solution formed by dissolving 0.287 Gm. of precipitated calcium carbonate (previously dried to constant weight at 200 C) in from 10 to 15 cc. of water containing 3 cc. of acetic acid and diluted to 250 cc. the turbidity produced by 1 cc. of the Dextrose Ringer's stock solution five times concentrated Abbott at the expiration of fifteen minutes is less than that produced by 1.25 cc. and greater than that produced by 1 cc. of the standard solution (limit of calcium $[Ca^{++}]$).

The dextrose content as determined by the optical rotation method of the U S P χ is not more than 26.82 Gm. anhydrous dextrose (29.5 Gm. $C_6H_{12}O_6 \cdot H_2O$) nor less than 24.26 Gm. anhydrous dextrose (26.7 Gm. $C_6H_{12}O_6 \cdot H_2O$) per hundred cubic centimeters. Treat 5 cc. of Dextrose Ringer's stock solution five times concentrated Abbott with an excess of sulphuric acid evaporate to dryness and ignite to constant weight at 750 C. the weight of ash obtained is not more than 0.242 Gm. nor less than 0.219 Gm.

Transfer 20 cc. of Dextrose Ringer's stock solution five times concentrated Abbott to a 100 cc. volumetric flask. Add water dilute to the mark and mix thoroughly. Transfer 10 cc. of this solution to a 400 cc. beaker. Add 50 cc. of water and 4 cc. of diluted nitric acid dilute to 200 cc. Add 15 cc. of silver nitrate solution. Heat to boiling and allow to stand until the precipitate is granular. Filter onto a weighed Gooch crucible previously heated to 140-150 C. Wash the precipitate well with hot water, dry to constant weight at 140-150 C. the chloride (Cl^-) calculated from the silver chloride weighed is not more than 2.1 per cent nor less than 1.9 per cent of weight of sample of Dextrose Ringer's stock solution five times concentrated Abbott.

DEXTROSE (See New and Nonofficial Remedies, 1933, p 267, THE JOURNAL, Feb 25, 1933, p. 574)

The following dosage forms have been accepted

Sterile 2½% Dextrose Solution in 1 cc. Container Each 100 cc. contains dextrose U S P 2.62 Gm.
Prepared by Don Baxter Intravenous Products Corporation Chicago (American Hospital Supply Corporation Chicago eastern distributor)

Sterile 7½% Dextrose Solution in 1 cc. Container Each 100 cc. contains dextrose U S P 7.85 Gm.
Prepared by Don Baxter Intravenous Products Corporation Chicago (American Hospital Supply Corporation Chicago, eastern distributor)

Sterile 20% Dextrose Solution in Vacoliter Container Each 100 cc. contains dextrose U S P 21 Gm.

Prepared by Don Baxter Intravenous Products Corporation Chicago (American Hospital Supply Corporation Chicago eastern distributor)

Sterile 25% Dextrose Solution in Vacoliter Container Each 100 cc. contains dextrose U S P 26.25 Gm.

Prepared by Don Baxter Intravenous Products Corporation, Chicago (American Hospital Supply Corporation Chicago eastern distributor)

CHLORBUTANOL (See New and Nonofficial Remedies, 1933, p 137)

Chlorbutanol (Hydrous)-Merck.—A brand of chlorbutanol-N N R. containing one molecule of water in two of chlorbutanol. This product is used in the preparation of aqueous solutions.

Manufactured by Merck & Co. Inc., Rahway N J. No U S patent or trademark.

Chlorbutanol (Anhydrous)-Merck.—A brand of chlorbutanol-N N R. For use in the preparation of oil solutions.

Manufactured by Merck & Co. Inc., Rahway N J. No U S patent or trademark.

NEOCINCHOPHEN (See New and Nonofficial Remedies, 1933, p 141)

Neocinchophen-Merck.—A brand of neocinchophen-N N R.

Manufactured by Merck & Co. Inc., Rahway N J. No U S patent or trademark.

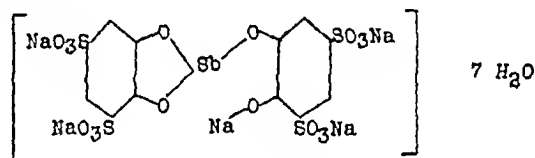

PRELIMINARY REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING PRELIMINARY REPORT

PAUL NICHOLAS LEECH, Secretary

FUADIN

Fuadin is a complex trivalent antimony compound (sodium antimony^{III} biscatechol-disulfonate of sodium), distributed by the Winthrop Chemical Company, claimed to have the following structural formula

It is proposed for use in the treatment of bilharziasis and granuloma inguinale in place of antimony and potassium tartrate. It is marketed in the form of a solution, in ampules containing about 63 per cent of the drug and representing about 85 mg of antimony per cubic centimeter. It is administered in doses of from 1.5 to 5 cc until a total of from 40 to 45 cc. has been given.

When the paper by Williamson, Anderson, Kimbrough and Dodson on 'The Specific Effect of Fouadin' (Fuadin) on Granuloma Inguinale' (this issue, p 1671) was submitted to THE JOURNAL, the editor informed the authors that the product must be submitted to the Council before the paper could be accepted for publication. After some delay, the Winthrop Chemical Company made formal presentation of the product for the Council's consideration.

Name.—The Council's Committee on Nomenclature considered the name Fuadin (named after Fuad I, king of Egypt because of his interest in the product). The committee felt that the name is regrettable, since it introduces the consideration of patronage, which is not desirable in science, and besides gives no inkling of the chemical nature of the product. However, it was not found technically in conflict with the Council's rules and, since the firm for practical reasons hesitates to give it up, the Council voted to recognize it. The firm stated its intention of using the scientific (chemical) name on the label in conformance with the Council's rules.

Therapeutic Usefulness.—Fuadin was synthesized by H. Schmidt of Elberfeld for use in the treatment of bilharziasis. The pharmacology of this substance has to some extent been elucidated by Hammuda of Cairo and Weese of Elberfeld, who determined the limits of toxicity, these investigators, it is stated, found the compound safe in therapeutic dosage. The claim is advanced that Fuadin has practically no action on the vagus

(although slowing of the pulse is said to occur almost without exception in the therapeutic use) and that it is excreted chiefly in the urine, only slightly in the feces and not at all by the skin. Hassan determined the excretion during clinical administration. No data on toxicity and excretion were found in the published literature. Such data should be made available as soon as possible.

Khalil and his co-workers¹ have treated a large series of cases of bilharziasis with Fuadin with reported excellent results. Fuadin is said by these workers to be superior to antimony and potassium tartrate ("tartar emetic") in that it may be administered intramuscularly, side actions are less pronounced, and the course of treatment may be shortened.

Since 1913, granuloma inguinale has been recognized as an endemic disease in the United States; previous to then it had been looked on as chronic chancroids or tuberculosis of the genitalia. The disease is now known to be rather widely prevalent; it was studied in Brazil by Aragão and Vianna, it occurs in the West Indies and is quite common in the Dutch East Indies.

Fox² and Cole, Miskjian and Rauschkolb³ have published extensive reviews on the subject, including case reports. The disease appears to be chiefly venereal, characterized by chronic granulomatous ulceration of the genitalia, occasionally with contact lesions on other parts of the body. Tissue smears stained with Giemsa's stain almost invariably reveal the presence of the so-called Donovan bodies, which are thought possibly to bear an etiologic relationship to the disease. McIntosh⁴ has suggested the "formaldehyde-gel" test as a diagnostic measure, while this is not specific, it is positive in a large proportion of cases.

In the past granuloma inguinale has been treated with antimony compounds chiefly in the form of antimony and potassium tartrate in 1 per cent solution intravenously, but only with moderate success. The disease tends to recur, often after the lesions are apparently entirely healed, smears made from biopsy material taken from the scar tissue may still reveal Donovan bodies.

In the work of Williamson and his co-workers, seven cases treated with Fuadin are reported in detail and seven others are mentioned, four of the former had previously been treated with antimony and potassium tartrate and one probably had been so treated all with poor results. In all seven cases the lesions were healed over after ten to twelve injections of Fuadin. The authors pronounced these cases cured. Unfortunately, no note is made as to the finding of Donovan bodies either before treatment was started or after healing apparently had occurred, the "formaldehyde gel" test of McIntosh similarly is not mentioned. These results are therefore open to criticism, it is not improbable that Donovan bodies may be found in the scars of these healed lesions, and these patients had not been followed for a sufficiently long time to rule out the possibility of relapse. It is unfortunate that more complete data apparently were not obtained in this study.

The authors compare Fuadin with antimony and potassium tartrate. Fuadin is described as a 'safe and rapid specific' although some of the patients receiving the injections are said to have had headache, nausea and vomiting; antimony and potassium tartrate is considerably disparaged—the referee believes undeservedly. The occurrence of the aforementioned and other symptoms, such as pain in the bones, which the authors have also observed indicates that the administered amount of antimony is as large as may safely be used. Probably several thousand injections of antimony and potassium tartrate have been administered in the clinic of the Council's referee. He reported that occasionally a little coughing occurs and, once in a while, emesis when properly given intravenously, "abscess and sloughing" never supervene, the referee has never seen fainting after injection. The authors describe, as late effects of antimony and potassium tartrate 'fever, continuous vomiting, jaundice and sudden death' aside from one

or two cases of mild icterus, no untoward late effects have been observed by the referee. He considers the comparison unfair. The development of white scars in the healing of the lesions is also mentioned, this is not uncommon in any inflammatory reaction in the skin of the Negro in which the lesion is deep enough to destroy the pigment layer.

No information was available to the Council's referee as to the effects of Fuadin on the kidneys. As antimony compounds are known to be renal irritants, caution is indicated until this phase of the problem has been properly elucidated. The use of Fuadin in granuloma inguinale is still in the experimental stage, the data presented in the paper of Williamson et al. are incomplete and must be supplemented by more complete reports before the therapeutic usefulness of Fuadin may be considered to be established.

As a result of its consideration of Fuadin, the Council held that the use of this drug in granuloma inguinale is still in the experimental state and that great caution is necessary in its use. The Council therefore postponed further consideration of the product until confirmatory evidence of its therapeutic value becomes available. If such evidence becomes available, the A. M. A. Chemical Laboratory will be asked to investigate the product with a view to elaborating standards. In order that Fuadin may be introduced for experimental use by qualified investigators, the Council authorized publication of this preliminary report in the same issue of THE JOURNAL in which the report of Williamson and his associates appears.

REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING
REPORTS

PAUL NICHOLAS LEECH, Secretary

PANCRESAL TABLETS NOT ACCEPTABLE FOR N. N. R.

Pancresal Tablets, according to the label on specimens received from the distributor, Pancresal Sales Company, Inc., contain "the active principle of the pancreas combined with asparagin and activating Elektrolytes." Each tablet is stated to contain sodium bicarbonate, 0.124 Gm, dekamethylenediguanidin carbonate, 0.006 Gm, Asparagin, 0.124 Gm, "Pancracym," 0.156 Gm, and "Mineral-Vitamine," 0.590 Gm. Subsequently a letter was received from the manufacturer, Dr. Richard Weiss, Fabrik Pharmazeutischer Präparate G. M. B. H., Berlin, Germany stating that the tablets for the United States market had the following composition: sodium bicarbonate, 0.224 Gm, dekamethylenediguanidin carbonate, 0.006 Gm, Asparagin, 0.075 Gm, "Pancracym," 0.125 Gm, and "Mineral-Vitamine," 0.250 Gm. The "Dekamethylenediguanidin carbonate" is declared to be similar to "Synthalin" which is stated to be dekamethylenediguanidin hydrochloride but to be superior to it, no convincing evidence for the assertion is offered. The "Mineral-Vitamine" is stated to be composed of dried yeast, calcium lactate, dicalcium phosphate, sodium sulphate, magnesium citrate, potassium iodide and powdered thyroid. The "Pancracym" is stated to be prepared from pancreas glands by extracting them with acetone, acetone and ether and ether, and the residue dried and powdered. No evidence for the efficacy of this component was offered.

The effective agent in Pancresal Tablets probably is the dekamethylenediguanidin carbonate. It is unlikely that the pancreatic extract which is contained in the tablets is of any significant value, many attempts have been made to isolate a pancreatic extract that is efficacious when administered by mouth, but so far these attempts have not been successful. The scientific data that are presented by two advertising circulars for Pancresal Tablets are extremely inadequate and make it probable that the preparation has no value other than that imparted by the content of dekamethylenediguanidin carbonate. Insulin substitutes of no greater potency than that claimed for Pancresal Tablets are without practical value. They accomplish almost nothing and are harmful because they are an invitation to diabetic patients to depend on this inadequate therapy in place of an adequate and sane insulin therapy.

Pancresal Tablets are unacceptable for New and Nonofficial Remedies because they present an unscientific complex mixture.

2 Fox, Howard. *Granuloma Inguinale, Its Occurrence in the United States*. J. A. M. A. 87: 1785 (Nov. 27) 1926.

3 Cole, Miskjian and Rauschkolb. *Dermat. Ztschr.* 53: 127 (April) 1928.

4 McIntosh, J. A. *The Etiology of Granuloma Inguinale*. J. A. M. A. 87: 996 (Sept. 25) 1926. *Study of Etiology of Granuloma Inguinale*. J. Tennessee M. A. 19: 190 (Nov.) 1926.

of indefinite composition which is marketed with unwarranted claims under a noninforming therapeutically suggestive name and in a way to lead the diabetic patient to place false dependence on this form of inadequate therapy

The foregoing statement of the Council's action on Pancresal Tablets was transmitted to the Pancresal Sales Co., Inc. Since no reply was received from the firm, a letter was written after five months concerning the failure to reply. Subsequently a letter was received through the firm from Dr. Richard Weiss of Berlin. This letter was examined by the Council's referee and found to contain nothing which justified any essential change in the Council's statement concerning Pancresal Tablets.

Subsequent to the first consideration of Pancresal Tablets, inquiries were received by the secretary of the Council concerning the testimonials from physicians appearing in advertisements for the product. Inquiries were sent to the two physicians named in the advertisements concerned, asking whether the testimonials were authentic and whether at the time of receiving the letter the physicians still subscribed to the statements. The first physician replied in part:

I believe Pancresal has no merits that it is a fake. This Dr. Marlow who observed this case in my wards had been warned that diet alone will do all this without Pancresal.

Furthermore I am not the head of the diabetic clinic of the Unity Hospital and am not a lecturer at the Long Island College Hospital.

I would greatly appreciate if you will let me know the date of receipt of the Pancresal advertisement for I warned them on October 3, 1932, that I would take legal action against them if they used my name in the future.

The second physician replied:

The statement I made about the Pancresal Tablets was on April 12, 1932. At that time one of their detail men gave me samples of Pancresal which I gave to two of my patients. As I stated there was a reduction in the blood and urine sugar but I was not sure whether diet had anything to do with it. I did not receive any more tablets so I could not say anything definite.

"At present the issuance of the statement does not meet with my approval. I have just recently found out that they are using my indefinite statement in their advertisements. The only reason I wrote the statement was to get more samples."

From these replies it appears that the statements of the physicians have not even the value of uncontrolled testimonials in favor of Pancresal Tablets.

The Council voted to reaffirm the rejection of Pancresal Tablets for the reasons given.

IODOMIN NOT ACCEPTABLE FOR N N R

Iodomine is a product of the American Bio-Chemical Laboratories, Inc., recommended in the treatment of "catarrhal rhinitis otitis media catarrhalis bronchial catarrh" and other disorders of the ear, nose and throat. The American Bio-Chemical Laboratories, Inc., has exploited in this country a number of foreign products, among them Thymophycin, which was found unacceptable for inclusion in N N R, and has been the subject of several critical comments in *THE JOURNAL (J A M A)* 94 1164 [April 12] 1930, 96 359 [Jan 31], 860 [March 14] 1931. Propeptans, which the Council also declared unacceptable for N N R, Disulphamin, a preparation advertised with extravagant therapeutic claims under a high sounding but meaningless chemical designation (*J A M A* 95 1690 [Nov 29] 1930), and Kephrene, which is now before the Council.

In an advertising circular Iodomine is said to be "a five per cent sodium iodide solution containing traces of free iodine." It is furnished in ampules of 1 cc., intended for subcutaneous injection, to be given "on alternate days or twice weekly" for as many as twelve doses. Infants may receive 0.5 cc.

The following are some of the claims made for this preparation:

"Its pure iodine content is exceedingly low precluding the possibility of iodism or other untoward reactions. Iodomine is contra-indicated only in iodine anaphylactic conditions. The therapeutic and palliative value of Iodomine is predicated upon the presence of a distinct catarrhal condition of the ear, nose or throat. Its primary indications are therefore: Acute Catarrhal Rhinitis, Otitis Media Catarrhalis, Acute Bronchial Catarrh, also recommended as a nonspecific palliative measure in Hydrorrhea and Vasomotor Rhinitis. Coryza will as a rule yield to one or two treatments. Allergic Rhinitis rarely yields to less than six injections of Iodomine and may require as many as twelve."

A preliminary examination by the A M A Chemical Laboratory of the contents of Iodomine ampules purchased in the open market indicated the presence, in 1 cc. of the solution, of 1.2 mg. sodium iodide and 0.7 mg. free iodine, the total solids remaining after evaporation at 95 C. approximated the iodide content. It is concluded from this examination that, instead of being a 5 per cent solution of sodium iodide with a trace of free iodine, Iodomine is a solution containing about 0.12 per cent of sodium iodide and about 0.07 per cent of free iodine. These observations seem to show that the advertising contains gross misrepresentation of the amounts of active substance. It is particularly to be noted that the firm avoided conflict with the Food and Drugs Act by omitting mention of the iodide or iodine content on the carton and ampules.

Any aqueous solution of sodium iodide will, on standing, develop traces of free iodine, the impression conveyed that Iodomine represents an advance in the preparation of iodide solutions is unwarranted. It is said to be somewhat irritant on injection, this is not surprising, in view of the hypotonicity and elemental iodine content of the specimen examined.

It is claimed in the advertising circular that the "exceedingly low" pure iodine content precludes the possibility of iodism. This appears to suggest that the composition of Iodomine is such as to diminish the incidence of untoward reactions below that which may occur with similar dosage of ordinary sodium iodide. Naturally the incidence of toxic responses would be lower with a solution as dilute as the examination indicated Iodomine to be, than with similar use of an actual 5 per cent solution (the concentration claimed—but not found) of sodium iodide. On the basis of the determination quoted, the total iodine dosage administered in Iodomine would appear to be about 1.7 mg., given on alternate days or twice a week. This quantity of iodine, whether elemental or ionic, would not cause iodism and, in fact, could hardly have any important therapeutic effect. The only well established consequence of such dosage is a gradual storage of iodine in the thyroid gland.

Periodically, the parenteral administration of iodine compounds, simple or complex, is reintroduced into therapeutics, usually with fantastic claims. The fact that the inorganic iodides, particularly the sodium and potassium salts, are readily absorbed from the intestinal tract and can produce all the known iodide effects when administered by mouth (except the more severe anaphylactoid effects of intravenous injection) seems to be overlooked by the popularizers of these remedies.

The parenteral use of small doses of iodine in the conditions for which Iodomine is recommended appears to have originated with H. Sternberg of Vienna (*Monatsschr. f. Ohrenh.* 64 401 [April] 1930). His preparation, manufactured by Chemosan, A. G., was introduced in Europe under the name 'Rhinostop'. It was said to have the same composition (5 per cent sodium iodide with a trace of free iodine) as that claimed for Iodomine. Sternberg inclined to the opinion that the free iodine administered was the chief factor in the therapeutic effect, even though the dosage amounted to only a few hundredths of a milligram, the evidence for this is far from convincing. The only American literature on the use of Iodomine available to the Council is a report (Rosenberg, *J. Laryngoscope* 42 883 [Nov.] 1932), without case histories, in which the indicated results are no better than other workers have claimed for the oral administration of sodium or potassium iodide or for other treatments. In fact, assuming that the Iodomine used by the author was similar to that examined by the A M A Chemical Laboratory, the small doses administered could hardly have acted as more than a placebo.

This apparently is another example of the exploitation of a well known drug under a proprietary name with misrepresentation of the content of active substance. A variety of unsubstantiated claims are put forth which seem to convey the impression that the manufacturer by some special process has endowed this simple mixture with exceptional therapeutic virtue.

The Council declared Iodomine unacceptable for inclusion in N N R because it is apparently a simple solution of two well known therapeutic substances (rules 1 and 2), because it is marketed under an uninformative proprietary name (rule 8) with unwarranted and extravagant therapeutic claims (rule 6), and because it is an unscientific preparation apparently containing active ingredients in ineffective quantities and in irrational proportion (rule 10).

Committee on Foods

REPORTS OF THE COMMITTEE

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

RAYMOND HERTWIG Secretary

CALUMET BAKING POWDER COMBINATION TYPE

Manufacturer—Calumet Baking Powder Company, Inc., Chicago

Description—Baking powder containing corn starch, sodium bicarbonate sodium aluminum sulphate calcium acid phosphate and 0.15 per cent dried egg white

Manufacture—The raw materials and ingredients used are purchased under definite specifications for composition, purity, granulation, etc., all of which are checked analytically by the company laboratories to assure conformity with specifications and food law requirements

Definite quantities of the ingredients are carefully weighed out and thoroughly mixed in mechanical mixers the mixture is examined in the laboratory to assure proper mixing and tested for total and available carbon dioxide. A test baking check is made on each individual batch. The baking powder is automatically packed in tins

Analysis (submitted by manufacturer) —	per cent
Total carbon dioxide (CO ₂)	14.7
Residual CO ₂	0.5
Available CO ₂ under baking conditions	14.1
Phosphorus (P)	3.7
Aluminum (Al)	2.2
Calcium (Ca)	2.2

Claims of Manufacturer—For use in baking and cooking recipes calling for baking powder. The product and ingredients conform to the respective United States Department of Agriculture definition and standard. The two acid reacting ingredients for liberation of the leavening gas, because of their different solubilities produce a "double leavening action" in the dough. The first action releases a portion of the leavening gas in the cold dough the second releases the remaining gas in the heated dough in the oven

LIGHT'S BEST OVEN PERFECT FLOUR (BLEACHED)

Manufacturer—Light Grain and Milling Company, Liberal, Kan

Description—Hard winter wheat patent flour bleached

Manufacture—Selected hard winter wheat is cleaned tempered and milled by essentially the same procedures as described in THE JOURNAL, June 18 1932 p 2210 Chosen flour streams are blended and bleached with nitrogen trichloride (one-seventh ounce per 196 pounds)

Claims of Manufacturer—For baking bread, biscuits and pastries

H G F STORES CRYSTAL WHITE SYRUP (85 PER CENT CORN AND 15 PER CENT ROCK CANDY SYRUPS)

SUMMER GIRL BRAND CRYSTAL WHITE SYRUP

(85 PER CENT CORN AND 15 PER CENT ROCK CANDY SYRUPS)

Packer—D B Scully Syrup Company, Chicago

Distributor—The H D Lee Mercantile Company, Kansas City and Salina, Kan., and Waterbury, Conn

Description—Table syrups, corn syrup base (85 per cent) with rock candy syrup (15 per cent), the same as Crystal White Syrup (85 Per Cent Corn and 15 Per Cent Rock Candy Syrups) (THE JOURNAL, April 15, 1933, p 1174)

THE NEW PETTIJOHN'S ROLLED WHEAT WITH ALL THE BRAN

Manufacturer—The Quaker Oats Company, Chicago

Description—Flaked cut whole wheat

Manufacture—Selected soft wheat is cleaned of weed seed, chaff and other extraneous matter and scoured, the individual wheat groats are machine cut into several pieces. The cut wheat is steamed, flaked between steel rolls and packed in cartons

Analysis (submitted by manufacturer) —	per cent
Moisture	11.9
Ash	1.6
Fat (ether extraction method)	2.1
Protein (N × 5.7)	11.8
Crude fiber	2.2
Carbohydrates other than crude fiber (by difference)	69.2

Calories—35 per gram 99 per ounce.

Claims of Manufacturer—A whole wheat breakfast cereal

"SWEET TOOTH" BUCKWHEAT PANCAKE FLOUR

Manufacturer—Black Bros Flour Mills, Beatrice, Neb

Description—Self-rising buckwheat pancake flour containing buckwheat flour, wheat "clear" flour white corn flour, calcium acid phosphate, sodium bicarbonate, salt, corn sugar and powdered skim milk

Manufacture—The ingredients are separately weighed, mixed in a batch mixer and automatically packed in paper bags

Analysis (submitted by manufacturer) —	per cent
Moisture	11.1
Ash	6.4
Fat (ether extraction method)	2.7
Protein (N × 6.25)	11.8
Reducing sugars as dextrose	0.6
Sucrose (copper reduction method)	1.2

Carbohydrates other than crude fiber (by difference)	66.4

Calories—34 per gram 97 per ounce.

Claims of Manufacturer—For making pancakes

- MADICO MALTOSE-DEXTRIN (PLAIN) ("A")
- MADICO MALTOSE-DEXTRIN WITH 2 PER CENT OF SODIUM CHLORIDE ("B")
- MADICO MALTOSE-DEXTRIN ("C") WITH POTASSIUM BICARBONATE 3 PER CENT

Manufacturer—Malt-Diastase Company, Brooklyn

Description—(a) Canned spray dried extract of malted barley and starch infusion, contains essentially maltose and dextrins

(b) Same as (a) with 2 per cent added sodium chloride.

(c) Same as (a) with 3 per cent added potassium bicarbonate.

Manufacture—(a) Diastatic barley malt of known diastatic power is crushed and admixed with gelatinized starch and water. The malt diastase is permitted to convert the starch at a definite temperature until a desired ratio of maltose and dextrins is obtained. The mixture is heated to boiling to stop diastatic action and coagulate precipitated protein and filtered to remove coagulated protein fat and insoluble material. The filtrate is concentrated in "vacuum" decolorized with activated carbon spray dried and automatically packed in tins

Analysis (submitted by manufacturer) —	per cent
(a) Moisture	2.2
Total solids	97.8
Ash	0.8
Fat (Roese-Gottlieb method)	0.04
Protein (N × 6.25)	1.2
Reducing sugars as anhydrous maltose	53.7
Dextrins (by difference)	40.9
Acidity as lactic acid	0.2
Carbohydrates (by difference)	95.6

(b) and (c) Same as (a) excepting as changed by addition of 2 per cent sodium chloride and 3 per cent potassium bicarbonate, respectively

Calories—(a) 39 per gram, 111 per ounce.

(b) 38 per gram 108 per ounce

(c) 38 per gram 108 per ounce.

Claims of Manufacturer—Carbohydrate supplements for the general diet of infants and for invalids

POLAND WATER

NATURAL SPRING WATER

Distributor—Hiram Ricker and Sons, Inc., South Poland Maine

Description—Spring water of very low mineral content and almost free from bacteria

Collection and Bottling—The Poland Spring is located in Androscoggin County, Maine, north of Portland. The immediate surroundings of the spring are red granite and are well cared for and sanitary. The temperature of the water, 5 C is uniform throughout the entire year. The spring outlet is within a large granite building and is covered with a glass case to prevent contamination. The water flows by gravity to granite storage tanks and to the bottling plant through quartz, glass and silver pipes. The tanks are glass covered and all vents are metal gauze covered. The water is bottled by automatic filling and capping machines. The air in the bottling room is filtered. The bottles before use are immersed in strong alkali solution for from one and one-half to three hours and are carefully washed, rinsed, steamed, rinsed steamed again and filled just as soon as cooled. The purity of Poland Water is regularly checked both chemically and bacteriologically.

Claims of Manufacturer—A pure spring water of low mineral content and almost free of bacteria

TAYLOR'S PRIDE LOAF

TAYLOR'S SANDWICH BREAD

Manufacturer—Taylor's Bakery, Columbia, S C

Description—White breads made by the sponge dough method (method described in THE JOURNAL, March 5, 1932 page 817) prepared from patent flour, water, sucrose, sweetened condensed milk, lard, salt, yeast, malt syrup and a yeast food containing calcium sulphate ammonium chloride, sodium chloride and potassium bromate

Claims of Manufacturer—Conforms to the United States Department of Agriculture definition and standard for white bread

FAIRWAY WHITE LABEL BRAND
TOMATO JUICE

Distributor—Twin City Wholesale Grocery Company, St. Paul, Minn., Minneapolis Minn., and Fargo, N D

Packer—The Loudon Packing Company, Terre Haute Ind

Description—Pasteurized tomato juice with a small amount of added salt, retains in high degree the vitamin content of the raw juice the same as Loudon Brand Tomato Juice (THE JOURNAL, June 25 1932, p 2289)

WHITE HOUSE NATURAL BROWN RICE

Manufacturer—Standard Rice Company, Inc., Houston, Texas

Description—Brown rice with the natural bran

Manufacture—The rough rice from the fields is passed over "shakers" to separate out foreign material and dehulled between shelling stones. The rice groat is separated from the hulls in special machines, air cleaned, heat or electrically treated for destruction of insect life and automatically packed in wax-paper wrapped cartons

<i>Analysis</i> (submitted by manufacturer) —	per cent
Moisture	13.0

Calories—35 per gram 100 per ounce

Vitamins—A fair source of vitamins A and G and a good source of B

Claims of Manufacturer—Contains the bran and nutritional values of natural brown rice

ROTH'S WHITE HEARTH BREAD

(POPPY SEED TOPPING)

Manufacturer—The A Roth Baking Company Newport, Ky

Description—A white hearth bread with poppy seed topping made by the sponge dough method (method described in THE JOURNAL, March 5, 1932 p 817), prepared from patent flour, water sucrose yeast, salt, malt syrup lard and a yeast food containing calcium sulphate ammonium chloride, sodium chloride and potassium bromate

Claims of Manufacturer—Conforms to the United States Department of Agriculture definition and standard for white bread

FAIRWAY WHITE LABEL EVAPORATED
MILK (STERILIZED)

Distributor—Twin City Wholesale Grocery Company, St. Paul

Packer—The Oatman Condensed Milk Company, Dundee, Ill

Description—This canned unsweetened evaporated milk is the same product as Oatman's Brand Evaporated Milk (THE JOURNAL, April 16, 1932, p 1376)

"SWEET TOOTH" PATENT FLOUR BLEACHED

Manufacturer—Black Bros Flour Mills Beatrice Neb

Description—A moderately hard winter wheat patent flour bleached

Manufacture—Selected dark Turkey red and hard winter wheat are cleaned, washed scoured and milled by essentially the same procedure as described in THE JOURNAL June 18 1932, page 2210. Chosen flour streams are blended and bleached with nitrogen trichloride (one-ninth ounce per barrel)

Claims of Manufacturer—For bread baking

WHITE HOUSE BRAND CORN FLAKES

Manufacturer—Standard Rice Company, Inc., Houston Texas

Description—Cooked flaked and toasted corn (free of germ and bran) flavored with sugar, salt and malt syrup

Manufacture—Corn hominy grits admixed with the formula quantities of sucrose, salt malt syrup and water are placed in sealed steel drums and steam cooked. The cooked mass is cooled broken into separate granules and dried to a moisture content suitable for their flaking between steel rolls. The flaked corn is toasted in revolving ovens is passed over screens to remove fine material and packed in wax-paper wrapped cartons

<i>Analysis</i> (submitted by manufacturer) —	per cent

PHYSICAL UNFITNESS IN STUDENTS

In his essay on the Prolongation of Life, Metchnikoff wrote, many years ago "If hygiene was able to prolong life when it was little developed, as was the case until recently, we may well believe that, with our greater knowledge of today, a much better result will be obtained." This expectation has in part been realized, indeed, it has been said that to hygiene belongs without doubt the place of honor in modern medicine. Public hygiene, or preventive medicine, as it is more frequently designated, represents a sort of offensive warfare against the noxious agents of our environment. Governmental activities protect mankind in the mass at every turn. They are concerned with pure air, pure water, pure food and the menace of epidemic disease. It may be doubted, however, whether personal hygiene, the defensive branch of public health service, has made equally notable progress. Do men exercise adequately the powers that may be developed for the strengthening of the individual? Is the hygiene of nutrition and of activity, including the perfect balance of work, play and sleep, appropriately cultivated?

The skepticism that leads to these questions has repeatedly been exhibited of late by students of physical fitness. It formed the theme of an essay by Emerson¹ of Tufts College Medical School in Boston, who has made extensive observations on the youth of preparatory schools and colleges. He asserts that the physical unfitness of these groups was indicated by higher mortality risks, as shown by the medico-actuarial table, and by increased morbidity and lessened efficiency, as evidenced by failure to withstand the pressure of curricular and extracurricular activities. Further evidence of physical unfitness among underweight students was shown by the marked increase of physical defects, by the correlation of underweight and self rating in health, and by the greater number of faulty health habits. Furthermore, a checking up of twenty faulty health habits of 4,366 students at the time of their admission to college shows no improvement during

the seven-year period 1924-1931. There is little difference between students from public high schools and those who prepared in private schools.

In formulating decisions of this sort, much depends on the selected criteria of health and fitness. Emerson lays stress on deviations from the standards of size that he has set up. He firmly avers that marked deviation from the optimal weight zone for any person cannot occur without an adequate cause, namely, either physical defects or faulty health habits. Emerson² ventures the following pronouncements. Increase in morbidity is evidenced by the fact that most of the sickness during college life occurs in two groups: respiratory diseases among the underweight and digestive disturbances among the overweight. Lowered resistance appears not only in relation to the incidence of diseases and of nervous disturbances but also in the failure to withstand the pressure of athletic training and of other extracurricular activities. Lessened efficiency is shown by the fact that the highest percentage of failures in preparatory school and college occurs in the seriously underweight and overweight groups. Further evidence of the significance of underweight is shown by the marked increase in physical defects and deformities³ in this group and by the correlation of safety and danger zone weight to self rating in health.

There may be considerable debate as to the serious role assigned to what are called faulty health habits. In Emerson's judgment, the four leading faulty health habits, for each college class, with a single exception, were no rest periods, fast eating, irregular bedtime, and the habit of having no regular time for bowel movement. Emerson's study of the health of students in eight representative high schools and seven leading private schools shows conditions of physical unfitness closely approximating that found among students entering college. He further alleges that private schools equipped with physical plants, gymnasiums, play grounds, medical staffs, and special teachers of physical administration and dietetics, and with all conditions favorable for carrying out the present accepted health programs, show a greater degree of physical unfitness and a higher percentage of faulty health habits than do the high schools.

Such incriminations call for earnest consideration. The American school and college boy need not become the victim of hygienic indifference, if the current indictments are tenable. Part of the responsibility is placed on the shoulders of medicine. The chief obstacle to health work, Emerson claims, is the persistent idea that if a person is not sick he is well, which prevents the physician from entering the field of health in the same scientific spirit in which he meets the problems of disease. Because of the failure of present health programs as indicated by the extent of physical unfit-

ness, the plea is made that medical training should be as efficient in the diagnosis of health as in that of disease. The physician, Emerson concludes, should become the leader and not the follower of lay workers in the field of health. He should become as much an authority in health as in disease. The technical part of physical fitness work, Emerson adds, is largely educational, but its supervision requires efficient training, which thus far has been given little place in medical teaching.

PROTEIN AND CALORIES

Much attention has been devoted in recent years to the problems of the food requirement at all ages and under the differing conditions of bodily activity that necessarily affect it. As a consequence there is widespread agreement as to energy needs. Concerning the factors governing the energy requirements of children, the reports of the White House Conference¹ point out that because energy is an old story and because rare instances have been discovered in which nutritional failure has resulted from the restricted choice of foods, even when total quantity was plentiful, there has been a tendency in some quarters to regard calories as of no further importance. It requires, the report continues, only the stress of some major calamity such as war or flood or an economic emergency, however, to revive the realization that supplying enough to eat to a population means a sufficiency of calories as well as that freedom of choice which is the everyday guaranty of quality (vitamins, minerals, amino acids).

The difficulties of formulating a warranted opinion about the desirable protein allowance in the diet are somewhat more formidable. Referring to children, Wait and Roberts² have remarked that this is so because there is no simple outward method of judging whether the protein ingested is too much or too little to meet the child's actual needs, as there is in the case of calories, with which a consistently excessive or deficient intake is reflected in gain or loss of body weight. It is true that normal growth will not occur on a deficient protein intake, but there is no way of knowing what constitutes normal growth in any one child. Moreover, so many other factors affect growth that failure to grow cannot be attributed solely to a protein deficit. On the other hand, Wait and Roberts conclude, protein in excess of actual needs is oxidized as fuel or stored as body fat the same as carbohydrate, but there is no way of knowing the amount so used.

In the case of adults, the protein requirement has been gaged in several ways. First of all, the dietary habits of many persons in apparent good health have been recorded and the protein intake estimated on the

basis of this experience. Such a procedure assumes that the actual experience and customary habits of mankind are a good guide. A more scientific plan has been to make nitrogen balance studies on persons subsisting on regimens involving different levels of protein intake. An unduly low limit of nitrogenous intake soon betrays itself by failure of the body to maintain nitrogen equilibrium. From studies of the sort referred to it is possible, as Wait and Roberts point out, to arrive at the minimum intake necessary to maintain nitrogen equilibrium and positive nitrogen balance under given conditions. Here again, however, they add, it is difficult to determine the optimum amount required to keep the body in good condition year after year, or to ascertain the maximum amount the body can handle without ill results.

Balance studies are far easier to conduct on adults than on younger persons. For this reason, relatively few investigations on nitrogen balance have been made on children and almost none on adolescent girls of 12 or more years of age, and none of these definitely establish either minimum or optimum values. Recent researches³ at the Department of Home Economics, University of Chicago, on more than fifty girls from 10 to 17 years of age living under their accustomed conditions and eating a freely chosen diet indicated that the protein intake varied directly with the energy intake. An average of 12.4 per cent of the calories consumed came from protein, and this close relation between protein and calories is further indicated. The girls consumed on an average 1.64 Gm of protein per kilogram. The intake was definitely higher at the younger ages, amounting roughly to 2 Gm at 10 and 11 years, 1.5 Gm from 12 to 15 years, and 1.2 Gm at 16 and 17 years. If one takes these results in connection with the studies of the few balances on normal children and the intake previously reported, Wait and Roberts are inclined to regard these values as tentative minimum standards until further balance experiments have determined more accurately the protein needs of childhood.

The common practice of providing from 10 to 15 per cent of the calories in the form of protein is therefore justified by this study. The simplicity of this method suggests its practical use, especially in providing for groups, when it is assured that ample calories are being consumed, and when there is no necessity for restricting protein to bare requirements. The results recall a war-time warning of the late Sir William M. Bayliss. It may be noticed, he⁴ wrote in 1917, that chief stress seems to be laid in diet tables on the energy or calory value of the food. This is justified by the fact, already mentioned, that, if any reasonable kind of combination of foodstuffs is consumed, it will be found that, if taken in the amount necessary to afford the energy value, sufficient protein will be contained in it.

3 Bayliss, W. M. The Physiology of Food and Economy in Diet. London, Longmans Green & Co. 1917.

without further addition. Natural foodstuffs, even potatoes, contain more protein than is often supposed to be the case. Pure products extracted from parts of plants or animals, such as sugar or oil, are not likely to be made the sole articles of a diet. Bayliss put the matter thus: "Take care of the calories and the protein will take care of itself."

VITAMIN D AND WELL BEING

New problems in relation to the possible function of vitamin D in promoting bodily welfare continue to arise, despite the commendable progress of recent years. One concerns the uncertainty of the need of supplementing the diet with added vitamin D if it is liberally supplied with the appropriate mineral constituents, notably calcium and phosphorus. As long as there is a widespread impression of a possible shortage of the bone-forming elements under the current dietary regimens in this country, as Bernheim¹ has recently intimated, the effort to alter prevailing conditions will naturally persist. She ventures the assertion that general health is improved and recovery from disease aided when the optimum calcium supply and utilization are assured. Furthermore, Bernheim insists that utilization of calcium is ineffectual, even with a sufficient calcium intake, unless also the factors that control the absorption of calcium are adequate.

In the symposium on the present status of the knowledge of vitamins,² published a few months ago under the auspices of the American Medical Association, Clouse remarked that the question "Why does vitamin D increase mineral retention?" is often asked but so far has not been satisfactorily answered. Since both calcium and phosphorus are excreted largely through the intestinal wall as well as through the kidney, it is difficult, if not impossible, to say whether the increased retention is due to an increased absorption of mineral or to a decreased excretion. A third possible factor might be the deposition of greater amounts of calcium and phosphorus in the bones. Probably the vitamin exerts its influence not in any one direction but to some extent in all three directions.

In new studies on animals that were subjected over long periods to extreme calcium deprivation, Templin and Steenbock³ of the University of Wisconsin found that the introduction of moderate amounts of vitamin D into the calcium-deficient ration provided considerable protection from mineral losses in a parallel series of rats. Only about 65 per cent of ash was lost from the femurs. These losses present considerable improvement over the 10 per cent losses experienced in the absence of such supplementation. The condition of

the rats was otherwise improved by the presence of vitamin D. Weight losses were greatly reduced, the calcium content of the blood serum was increased, and the parathyroids were maintained almost normal in size.

Such results tend to support the impression of the value of vitamin D as a food constituent for the adult. When the vitamin is supplied in moderate amounts in connection with either a high calcium-low phosphorus rachitogenic ration or a low calcium-low phosphorus ration, calcium and phosphorus are conserved to a remarkable degree. The Wisconsin biochemists frankly insist that it is unwarranted to expect that vitamin D administered in any amount should be able to compensate fully for an extreme lack of calcium or other dietary essentials. As the basal diet was not optimal with respect to protein or phosphorus content, it is possible that the favorable effects of vitamin D on calcium conservation might have been accentuated if the diet had been improved in these respects also. This is equivalent to the much needed reminder that vitamins are by no means the sole essentials for a healthful diet.

Current Comment

URINARY AMMONIA

The body is an acid-producing mechanism. The oxidation of the carbon of the foodstuffs yields carbonic acid, and the metabolism of the sulphur and phosphorus of proteins results in sulphuric and phosphoric acids. Despite the constant formation of these acids, the acid-base balance of the body is so nicely regulated that during health the reaction of the organism remains remarkably constant at about p_H 7.4. One of the noteworthy contributions of biochemistry has been the demonstration of the mechanisms involved in maintaining the acid-base equilibrium. Thus the buffer systems of the body fluids act as a prompt though necessarily temporary defense against the increase in acidity, the ultimate removal of acid occurs through the lungs, kidneys and skin. Obviously there is a constant effort to conserve fixed base. The lungs excrete free carbonic acid, the sweat glands of the skin secrete lactic acid, to a considerable extent uncombined with base, and the kidneys, in addition to conserving base through a shift in phosphates, have the remarkable ability to supplant fixed base in excreted salts with ammonia. It has long been known that urinary ammonia, formed in the kidneys, increases when the need for removal of acid is accentuated. Indeed, an increased concentration of the so-called endogenous base has been taken as matter of fact to indicate acidosis. The ammonia in the urine arises from the urea, there exists a reciprocal relationship between these two nitrogenous compounds. What is the factor that governs the magnitude of the change of urea to ammonia? One naturally turns to the presence of elevated concentrations of metabolic acid as the most obvious cause. That this is not likely was pointed out in 1929 by Oard and Peters¹ on the basis of their

own studies and those of others on the alleged acidosis of pregnancy. The carbon dioxide and serum albumin concentrations are low with accompanying decrease in total base. Under these conditions a larger than normal proportion of total base in the urine is present as ammonia. That the available fixed base in the body is the primary factor in controlling the ammonia output in the urine is thus indicated. Further corroborating evidence is furnished in the observations of Brooke and Smith² on experimental animals maintained on rations extremely poor in total base. Under these conditions as much as 95 per cent of the base in the urine was accounted for by ammonia, whereas the value in normal control animals was less than 8 per cent. The importance of the proportion of the components of buffer systems has been emphasized because the strikingly constant p_H of the blood depends on it, these studies point out a sensitive mechanism in the kidney that is apparently responsive to the quantity of base in the buffer combinations in the circulation.

Medical Economics

PRIVATE GROUP PRACTICE

[This is the second part of a series of investigations conducted by the Bureau of Medical Economics of the American Medical Association. The first part was published in *THE JOURNAL* May 20.]

Every attempt to study private medical groups has been confronted with the almost impossible problem of defining the singularly elusive changing and indefinite characteristics of a group or even of giving it a name. The name most frequently used by the medical groups themselves and those discussing them is "clinic" but this title has been so generally applied to another also somewhat indefinite and even more common type of medical practice that it has been thought better to use the more general inclusive term of 'group'.¹

'Group' in this study designates three or more physicians who have joined for practice and who own certain kinds of equipment aside from office space and employ lay assistants in common. It is frankly admitted that this description is as indefinite as the object defined. The fact is that in almost every case the decision as to whether any particular group should be included has had to be made after a study of all available details as to organization and operation.

The study conducted by the Committee on the Costs of Medical Care² gives the following definition:

The private group clinic for the purpose of this analysis may be defined by several characteristic features—professional financial and administrative. (1) Its physicians engaged in cooperative and contiguous medical practice use many facilities in common, particularly office space, laboratories and medical equipment. (2) Its physicians—all or most of them—are associated with the clinic on a full-time basis. (3) Its services include two or more medical specialties and an attempt is usually made to hold available complete facilities for the patients accepted by the clinic, although some groups avowedly exclude from their services such specialties as obstetrics, ophthalmology, or dentistry. (4) Its patients are the responsibility of the entire group, not merely of individual physicians, although when consultations and special diagnoses are not required one practitioner may alone treat a given case. (5) Its income is pooled and its practitioners have little or no direct financial relationship with patients. (6) Its members determine individual incomes by contract among themselves rather than directly from their services to patients. (7) Its administration is carried on by a business man rather than a physician as far as non-medical matters are concerned. (8) Its credit investigations and collection policies are the specialized functions of a business manager rather than the incidental concerns of the several practitioners.

Considerable difficulty was found in strictly applying these qualifications to actual groups. The third qualification as to 'medical specialties' and 'complete facilities' would require a very liberal interpretation of these terms and of the word 'attempt' and a membership much larger and better organized in these respects than was required for admission even to the study based on this definition. The fourth one conflicts with the general claim made by perhaps a majority of the groups that individual relations and responsibility are maintained between physicians and patients. The fifth and sixth features make financial arrangements the fundamental characteristic. Moreover the wide variety of such arrangements, in which only certain portions of the income are 'pooled' and in which the division of income varies in almost every imaginable way, not only makes this test difficult of application but would include every partnership in which all transactions with patients are not on an exclusively individual basis. The seventh qualification is also too indefinite for application. Would it exclude the group using a woman secretary or even one of its medical members who was believed to possess exceptional business ability? How many and what phases of "administration" must be handled by a business man? The same difficulties are found with the final qualification as to 'credit investigations and collection policies'.

This difficulty of definition is due to the extreme indefiniteness of the thing to be defined which perhaps can be best illustrated by the steps which were taken to determine which groups should be included as proper subjects for this study. A preliminary questionnaire, sent to all secretaries of county medical societies was answered by 1,949 secretaries who listed over 500 organizations which they considered as coming under the classification of group practice. Additional lists from other sources raised the number to 724.

It has been argued that 'the closed staff hospital is in effect a group clinic,'³ and 1,165 such hospitals were listed by the Council on Medical Education and Hospitals of the American Medical Association. An effort was made to ascertain which of these possessed characteristics which required their inclusion within this study, although no special circularization of these was made. A questionnaire was sent either to the secretary of the county medical society or directly to each of the approximately 700 groups reported. When a reply was not received from the secretary the questionnaire was sent directly to the group. An examination of the replies with accompanying correspondence showed that, with few exceptions if the secretary was not a member of the group he either gave the questionnaire to the group or verified his reply by personal consultation of the members. The information on these questionnaires was then used as a basis for deciding whether the group should be included. In making this decision due attention was given to the standards set up by previous writers on the subject including those already discussed. A minimum membership of at least three was required although this excluded many associations of two physicians which had adopted some such name as 'clinic' shared ownership in somewhat extensive equipment 'pooled' the income according to fixed provisions had a 'business manager' and in other ways seemed to fit the qualifications.

That the superior publicity value of some such a title as 'clinic' has been generally recognized and adopted for competitive purposes without any attempt to conform to any definite standards is clear. One investigator of this type of practice said:⁴

there were found organizations designated as group clinics which on very slight investigation were found to be merely a trade name for the office of an individual physician who might have one or two assistants. A more worthy example listed among group clinics was found to be simply an association of two physicians sharing the expense of office facilities.

So-called 'diagnostic clinics' the main function of which is to do laboratory and other work for outside practitioners were excluded. No closed staff hospital was included unless the staff operated as a more or less organized group in private practice outside the hospital. Groups that appeared to be

primarily the industrial departments of a single industry were also excluded. The fact that many groups were changing form even while under observation made certainty of classification more difficult.

Letters and questionnaires brought information showing that about half of the 700 reported groups did not conform to a

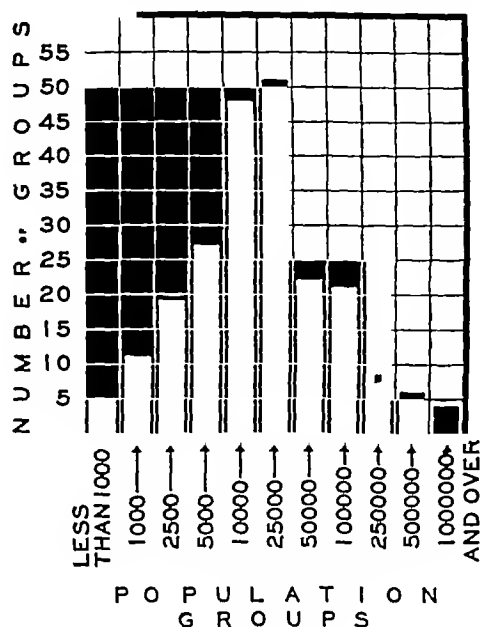

Chart 1—Number of groups according to size of community

sufficient number of the standards that had been set up to entitle them to inclusion in this study, although, as already mentioned, many of these called themselves "clinics" and were so considered in their localities. Many of these were partnerships of only two physicians or, if composed of a larger number, had little in common beside a reception room and telephone service.

From all the information received it was determined that there are over 300 groups in the United States that would come within the classification fixed by these standards. Of these, 239 filled out the questionnaire in a sufficiently complete form to make it available for study. That not only is this a fair sample but that no appreciable change would be produced in any of the conclusions by returns from those not replying is shown by the fact that an analysis of the first 100 received gave results as to averages and similar computations almost identical with those derived by more than doubling the number.

Although the Mayo Clinic cooperated fully in the study and furnished complete information it was decided that, owing to its wholly unique character its inclusion would distort all conclusions. Moreover, the organization and operation of this clinic has been so frequently and adequately described elsewhere as to make any discussion that could be given here superfluous.

GEOGRAPHIC DISTRIBUTION

One or more groups were reported from each of thirty-seven states, showing a very wide dispersion of this form of medical organization. The states from which no groups were reported were Connecticut, Delaware, Idaho, Maine, Maryland, Nevada, New Mexico, Rhode Island, South Carolina, Vermont and Wyoming. The states reporting ten or more groups were Texas, twenty-seven; Wisconsin, twenty-three; Minnesota, eighteen; California, seventeen; Indiana, thirteen; Illinois, eleven; and Washington, eleven. An analysis of the distribution according to the size of the cities shows at once that this form of practice offers no contribution to the problem of metropolitan medical service. Nearly 50 per cent of the groups are found in cities of less than 25,000 population, and over 67 per cent in those under 50,000, while a trifle over 4 per cent are located in cities above 500,000.

It is not easy to determine the reasons for this concentration of 67 per cent of the groups in cities under 50,000 with

but 21 per cent of the population. Even if the rural population dependent on these smaller cities is included, the disproportion is great.

Some suggestions as to the reasons for group formation appeared in the answers to the first questionnaire by secretaries of county medical societies. An effort to supply a lack of laboratory and hospital facilities was the avowed motive back of the formation of several groups in the smaller cities. Such a motive is not felt by the individual practitioners in the large cities with ample and easily accessible hospital and laboratory services. The very existence of extensive hospital, clinic and outpatient services provides medical care for many who, in a smaller place, would patronize a group.

Another possible element is the closer association of physicians in a small city. Groups are formed quite largely of personal friends, who have already been somewhat closely associated professionally. They have been referring patients to each other, and association in a definite group is often little more than formal recognition and systematic arrangement of previous informal relations.

In a large city the well known physician, particularly the specialist, builds up his own clientele and establishes relations with a large number of his confrères. The formation of a group, which could not include all those with whom he had such relations, would limit rather than extend his influence and his income.

The publicity and prestige which accompany the formation of a group in a city of less than 50,000 population, where such publicity depends so much on word of mouth dissemination is more conspicuous than in a metropolis, where the prestige of certain individual practitioners is apt to be greater than that of a group which lacks any especially outstanding personalities. A metropolitan group, deprived of this inherent local

publicity can secure an equivalent prominence only by some form of more or less direct advertising, a fact which removes from ethical practitioners one of the incentives to form a group.

AGE AND GROWTH

Any attempt to determine the rate of growth is met with an almost complete lack of information as to the mortality rate of groups. It is certain that a considerable number of groups

have been dissolved or have failed. The results of an effort to ascertain the reasons for such disappearances are given later, but all attempts to secure sufficient data to determine the average length of life or the annual rate of dissolution resulted in too meager returns to justify any conclusions as to rate of growth. Any such conclusions therefore, must be drawn almost wholly from the dates of founding of existing groups. This manifestly gives an exaggerated picture of the rate of growth, since it is probable that the mortality rate remains much the same each year and that, accordingly a larger percentage of those now operating were formed in recent years than of those established at an earlier period.

Bearing this consideration in mind it is noteworthy that only eighteen of the reporting groups were founded prior to 1912, in which year nine more of those now existing were established. The founding of groups is closely influenced by general economic conditions. There are peaks in the 'prosperity' periods 1918-1920 and 1927-1929 and corresponding declines in the 'depression' years that followed.

When the cumulative totals for each year were plotted on a logarithmic scale the line showing the rate of growth rose faster from 1914 to 1920 than the general trend. Since 1920 it has risen slower than the general trend. This would seem

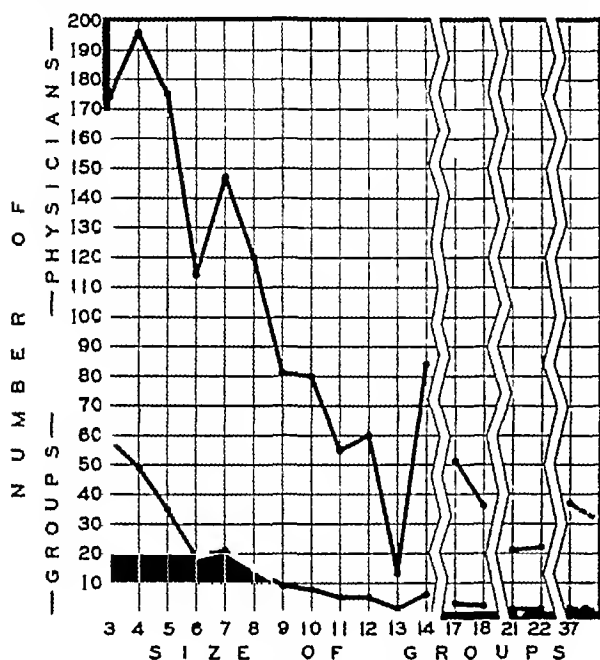

Chart 2—Number of groups and physicians according to size of group. Upper line physicians. Lower line number of groups.

to indicate a slowing up in the rate of growth, a conclusion that receives further support from the opinions of a majority of the secretaries of county medical societies.

Since the fact of this slowing of the rate of increase is by no means certain and if it does exist, may be a temporary phenomenon owing to special industrial conditions, it is probably too early to discuss its causes. But it may be suggested that the extension of laboratory and hospital facilities and the growth of outpatient departments with free and pay clinics may be setting limits to further extensive growth of private groups.

SIZE OF GROUPS

There were 239 groups that reported the number of physicians included. These had a total membership of 1,466 physicians and 96 dentists, an average of 6 physicians to a group. The median of membership falls between five and six members, and the average is, as just stated six. Less than 13 per cent of the groups have ten or more members, and these include but 30 per cent of the physicians in group practice, while 37 per cent of the physicians are found in groups with a membership of five or less.

Do the groups tend to become larger? This question may be put in two ways. 1. Have the older groups tended to

grow to greater and greater size? 2. Are the groups formed in recent years including a larger number of physicians? It is impossible to give a positive answer to either of these questions, but an analysis of the size of groups by years gives a strong suggestion of probable trends in these respects. If there is any general and regular tendency for groups to grow

TABLE 2—Number of Members According to Size of Group

by the addition of new members one should expect to find the largest groups among those first established. Of 38 groups with 212 members formed prior to 1916 only 1 has at present more than 10, only 2 others have as many as 10 members and the average membership is 4.6. With 1916 a period of rapid growth began that reached its peak in 1920, when 22

groups comprising 133 members were organized, after which the annual growth declined to 9 groups with 78 members in 1924. The total number of groups formed in this period of nine years was 88 with a total present membership of 641 or an average of 7.3 members per group. Beginning in 1925 there was another period of accelerated increase reaching in 1929, the same peak of 22 groups having 133 members and ending again with 9 groups and 78 members in 1932. The

total number of groups formed in this period of eight years was 104, with a membership of 544, an average of 5.2 members per group. This would certainly seem to indicate that the size of groups has been decreasing since the first period of rapid growth. When it is also considered that the population of the United States increased from 105,710,620 in 1920 to 122,775,046 in 1930 and the number of physicians from 145,404 in 1921 to 156,440 in 1931, it does not appear that the percentage of physicians entering group practice has increased during recent years. This conclusion is strengthened by the fact that if the mortality rate among groups has remained anywhere near constant the percentage of groups

as now in existence. Of these, 20, or a little less than one fourth, are incorporated. In the second decade 123 were organized, of which 17, or a little less than one-seventh, were corporations. Even considering the probability that the corporate form has attained one of its objects, a lower mortality rate, it would still seem that any tendency that may exist is away from the corporate form.

SPECIALIZATION WITHIN GROUPS

The principal argument offered in urging the extension of group practice is that a group assembles in one place all the essentials required for complete diagnosis and treatment of the patient. It is claimed that a group consists of a sufficient number of adequately trained specialists to permit reference to whatever specialist may be necessary for proper diagnosis and treatment. At least two writers have outlined what they consider the minimum composition of a group. The first⁵ after saying that 'a minimum number should be at least four' added "A surgeon, internist and E. E. N. & T. are indispensable. The fourth may specialize in x-rays and physiotherapy, urology, laboratory, pediatrics or other branches

TABLE 4—Running Average Size of Groups for Five Year Periods

1930	5.41
1931	5.19
1932	5.14

organized in the period 1916-1924 which have since disappeared must be greater than the corresponding percentage for the more recent period 1925-1932.

There is a well established statistical method of determining whether an apparent trend is consistent. This is the method of "running averages," by which the figures are grouped in regular intervals with the earliest year in the group dropped and an additional year added for each computation. The use of this method with groups of five, the first group ending in 1916, gave the results shown in table 4.

Here is an unmistakable trend line showing that according to year of formation the groups reached their peak as to size in the years 1918 to 1921 and have been steadily diminishing ever since.

This average is considerably modified by the presence of a single group, with thirty-seven members, organized in 1929, which differs quite widely in nearly all its characteristics from any other organization. It is primarily a "voluntary health insurance plan" and is so designated in a study made by the Committee on the Costs of Medical Care. If this single organization is omitted from the table, the last four cumulative averages would be as follows:

1929	5.0
1930	4.9
1931	4.7
1932	4.0

Standing alone, any one of these tests would probably be inconclusive, and if any one contradicted the others it would raise a doubt. But when all give the same reply there is every reason to say that so far from following the industrial trend toward greater and greater size, groups have for several years been growing smaller.

FORM OF ORGANIZATION

While there are individual variations in detail, the organizations are of three general types: partnerships, corporations and individual ownership. By far the largest number are partnerships. Of 227 replying to the question on the form of organization, 140 were partnerships, 45 corporations and 42 individually owned. It is difficult to secure any conclusive evidence of any tendency of one of these forms to supplant either or both of the others. There were two decades in which the progress of group formation was exceptionally rapid—from 1912 to 1921 and from 1922 to 1931 inclusive. Of the groups formed in the first period, eighty-two were reported

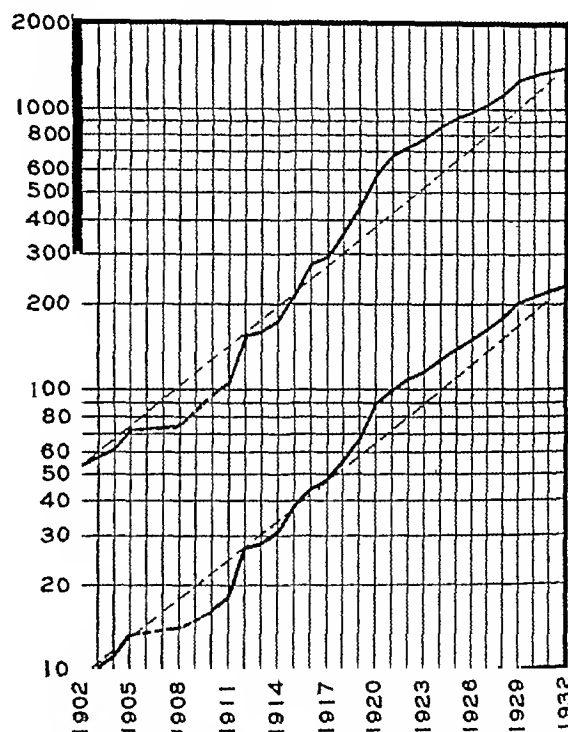

Chart 3—Growth of groups by years. Upper line total number of physicians—lower line number of groups. Trend lines dotted.

Pediatrics is a happy choice, since this branch is most important and one of the most neglected in smaller communities." A somewhat higher standard is set by the other writer "Every group should comprise, at least, an internist, a surgeon and a gynecologist, a pathologist, a roentgenologist, a urologist and proctologist, a specialist in eye, ear, nose and throat diseases, a dentist and a trained nurse."

Information as to the specialties practiced was furnished by 223 groups having a membership of 1,357 physicians and 90 dentists. The distribution of specialists within these groups as reported by the groups themselves is shown in table 5. When a physician reported that he practiced two specialties, each was counted as one-half. In the few instances when a claim was made that a physician practiced more than two specialties, all but the first two were discarded. The inclusion of these, with corresponding fractions would not have materially affected the totals.

The table as it stands, would appear to indicate a more minute subdivision and consequent inadequacy of representation.

⁵ King, D. D. Group Practice in the Smaller Communities, Nebraska M. J. 10: 220 (June) 1925.

tion in certain fields than it is perhaps fair to assume in the average group. There are certain specialties that are recognized as so closely related that their combination in the same person is not only possible but often desirable. These combinations have been made in table 6 which, accordingly, gives a fairer view of specialization among group members and the representation of the specialties in the various groups than is given by table 6

* Each counted as one half in total

The first impression which is confirmed by all analysis is that there is no general standard or typical of groups. Although there are 313½ physicians wholly or partially in surgery only 197 out of 223 include one of these among its members, 238½ partial, specialists in internal medicine are found in 109 groups and 207 general practitioners are members of 133 groups or less than one-half the total number

indicate any tendency of groups to organize around general practitioners. The preponderance of surgeons raises the question of whether there may not be some justice in the charge sometimes made by critics of group practice that many groups are formed only to act as "feeders" for successful surgeons.

The fourth largest number of specialists are those dealing with conditions of the eye ear nose and throat. There are 184 complete and 7 partial specialists in this field and they are represented in 139 groups. The fifth class as to size is composed of obstetricians and gynecologists, of whom there are 62 complete and 81 partial specialists, represented in 109 groups.

The number in each of the other specialties is too small to supply even a partial specialist to one half of the groups.

That there is no standard composition of groups and no such distribution of specialists among the groups as to make possible the assemblage, in any large percentage of the groups, of the specialists required for complete diagnosis and treatment is evident.

If one takes, for illustration, the 147 physicians found in groups with 7 members and attempts to arrange them to form

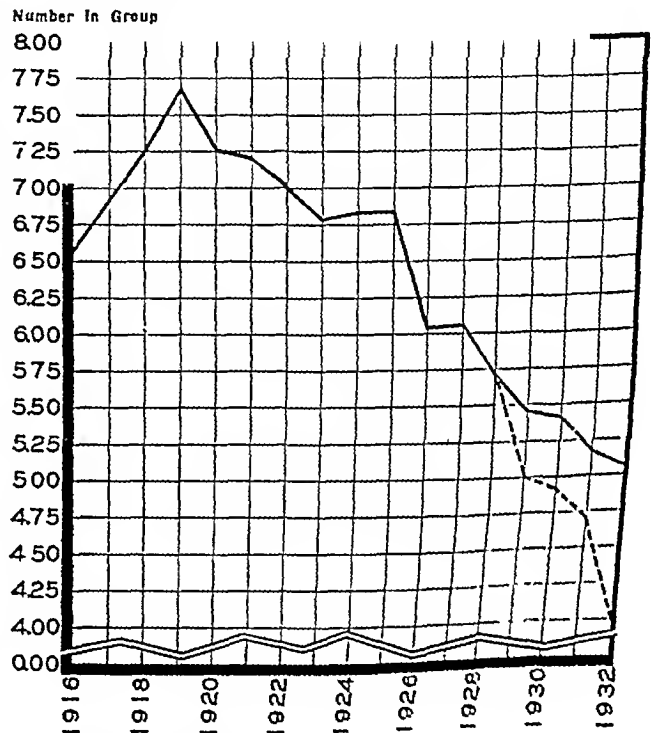

Chart 4—Changes in size of groups by years. (Dashed line with omission of one group. See text.)

the 21 groups of this size it is a very apparent that it is impossible, even with complete unrestricted power, to distribute these physicians in such a way as to form 21 groups capable of rendering a complete medical service.

This statement is based on a certain type of group practice but it is a reminder of the excessive claims that have been advanced for the group practice and the opposition contrary to the fact that there is a standard type to which all groups approximate.

It is possible to make adjustments as to the qualifications of some of the members of a group practicing a specialty in which there are specialists. Among the point to be considered is the fact that such qualifications as would be required of a specialist in a specialty which would at least include one or more of the specialties in the group.

Four of these could be determined by the names of the specialists in the group and 95 partial specialists in the group. The names of the specialists in the group would determine the extent of the group's health

1931 directory, the latest edition. These are probably young physicians or those who have recently been licensed.

Of the remaining 309 there were 291, or 94 per cent, who were members and 211, or 68 per cent, who were Fellows of the American Medical Association. Two hundred and fifty-three of these were listed as specialists in some department of surgery and fifty-six as general practitioners. There were 166, or 54 per cent, who were members of 1 or more special societies and 143 who did not belong to any such society. Of these memberships 164 were in the American College of Surgeons, 14 in the Southern Surgical Society, 9 in the Western Surgical Association, 5 in the American Surgical Association, 4 in the Pacific Coast Surgical Association, 4 in the New England Surgical Society, 2 in the Associated Anesthetists of the United States and Canada and 1 in the Society of Neurological Surgeons.

The next largest group of specialists which it is possible to classify in this manner is composed of those treating the eye, ear, nose and throat. Of 184 complete and 7 partial specialists in this field the names of 144 were given, of which there were 141 listed and 3 not listed in the 1931 directory. Of these 141, 139 were members and 101 Fellows of the American Medical Association. One hundred and sixteen are listed in the directory as specialists and twenty-five as general prac-

tory, and 34 did not answer this question. Of the eighteen there were eight that said they used a laboratory in a hospital, which was usually owned or controlled by the group. Some of the others listed equipment owned by the group although they did not call the office a laboratory. Such equipment has been included in the totals.

There were 213 groups that stated they had roentgenologic equipment, 65 an electrocardiograph, 190 some material for physical therapy treatment and 192 apparatus for testing metabolism. Eighteen groups reported the possession of varying quantities of radium. It must be at once recognized that these bald enumerations are far from giving any accurate picture of the scientific equipment of medical groups. Comment accompanying these replies showed that there is the widest variation in the character of this equipment. Roentgen equipment, for instance, varies from the simplest single machine to a whole battery of several types, including those required for high voltage therapy and other radiant treatments. The variation is perhaps even wider in the department of physical therapy. Some groups have little more than a simple infra-red lamp, while others reported elaborate apparatus for all forms of treatment. It can only be said that these replies indicate that there is nothing approaching standardization in regard to the equipment required in group practice. Further

tioners. Seventy-one are members of some special society and seventy hold no such membership.

There were forty-nine complete and seventeen partial specialists in urology. The names of fifty-eight of these were given of whom fifty-four were members and forty-one Fellows of the American Medical Association. Fifty of these were listed as specialists and eighteen as general practitioners. Twenty-four were members of special societies and thirty-four held no such membership.

Owing to combinations and natural affiliations between the different specialties which make any classification as to listing and special societies apt to be misleading no attempt has been made to analyze these facts in regard to obstetricians, gynecologists and pediatricians. The number of specialists in other lines is so small that such an analysis would mean little.

There was a total of 1,079 physicians in group practice whose names were returned on the questionnaires. Of these 1,019 were members and 719 Fellows of the American Medical Association, and only 60 nonmembers. Expressed in percentages, this would indicate that 94 per cent of the physicians in group practice are members and 66 per cent Fellows of the American Medical Association.

EQUIPMENT

Of the 239 groups that returned the questionnaire, 217 stated that the group owned, and 18 that they did not own a labora-

tory, and 34 did not answer this question. Of the eighteen there were eight that said they used a laboratory in a hospital, which was usually owned or controlled by the group. Some of the others listed equipment owned by the group although they did not call the office a laboratory. Such equipment has been included in the totals.

OWNERSHIP OR CONTROL OF HOSPITAL

There are usually very close relations between the group and some one hospital, although a number of reports stated that all the local hospitals were used. Of 237 groups replying to the question regarding relations with hospitals 76 stated that the group or one of its members owned or controlled a hospital or, in a few cases the hospital corporation owned the group. Of the 161 groups which stated they did not directly own or control a hospital there were 22 in which all the members of the group were on the staff of some one hospital. Two reported that the group owned stock in a hospital, and another that the group had its offices in a hospital.

Since the latter comments were largely in the nature of volunteered information, it is probable that similar relations exist with many other groups that do not directly own or control hospitals.

FINANCIAL RELATIONS WITH PATIENTS

There were 225 groups that replied to the question "Are patient's financial relations with group or with individual physicians?" Of these, 175 stated that such relations were with the group 47 with individual physicians and 3 with both. These answers were modified by comments from those stating that relations were with the group to show that in nineteen groups there were certain financial relations with the individual physicians. Similar modifications indicated that in eight of the groups in which the relations were primarily with individual physicians certain charges generally those for laboratory or industrial work, were handled by the group.

In order to ascertain whether the nature of these relations was determined by the size of the group a further analysis was made of those groups in which the relations were with the individual physician. It was found that the average size of such groups was six and five-tenths as compared with an average of six for all the groups covered by the study. Among these forty-seven were groups with fifteen seventeen twenty-one and twenty-two members. Their operation in all medical matters was in no way distinctive or different from those in which financial relations were with the group. Pooling of income and its distribution according to some arbitrary predetermined plan seems to have nothing to do with the question of the quality, method of giving or other characteristics of medical practice.

No tendency is apparent toward a general adoption of a policy of pooling or of retaining individual financial arrangements. Comparison of the dates of formation of the groups with individual relations show that these constitute about the same percentage of the total number at all times during the last twenty years.

(To be continued)

Association News

THE MILWAUKEE SESSION

Annual Meeting of Medical Veterans of the World War

The annual meeting of the Medical Veterans of the World War will be held at 9 p. m., Wednesday, June 14, at the Eagles Club Milwaukee. There will be an informal smoker reception and luncheon. Dr. Gilbert E. Seaman, 324 East Wisconsin Avenue, Milwaukee is the chairman of the committee in charge of arrangements for this meeting. Members of the Association of Military Surgeons and all medical veterans of the World War, including physicians who served as medical advisers to government units and draft boards, are invited to attend.

University of Wisconsin Medical School Alumni Dinner

Alumni of the University of Wisconsin Medical School will have an old fashioned German dinner and reunion at the Wisconsin Club on Wednesday, June 14 at 6:30 p. m. All physicians who have been affiliated with the medical school for two or more years are invited to attend. Reservations should be made through Dr. Chester W. Long, 208 East Wisconsin Avenue, Milwaukee, as early as possible.

MEDICAL BROADCAST FOR THE WEEK

American Medical Association Health Talks

The American Medical Association broadcasts on Tuesday and Thursday from 9:15 to 9:20 a. m., Chicago daylight saving time, which is one hour faster than central standard time over Station WBBM (770 kilocycles or 389.4 meters). The subjects for the week are as follows:

May 30 Holiday No broadcast
June 1 Pains and Pills

There is also a fifteen minute talk sponsored by the Association on Saturday morning from 9:45 to 10 o'clock over Station WBBM. The subject for the week is as follows:

June 3 Allergy in Childhood I

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES NEW HOSPITALS EDUCATION PUBLIC HEALTH, ETC.)

ALABAMA

Society News—Dr. Charles Marshall Hamilton and Dr. Wilder Walton Hubbard, Nashville, Tenn., spoke before the Lauderdale County Medical Society, April 4, on diseases of the skin and pneumothorax in the treatment of tuberculosis, respectively.—Dr. Gerald G. Woodruff, Anniston, addressed the Calhoun County Medical Society, April 4, on "Blood Pressure in Pregnancy."—Dr. Andrew L. Glaze, Jr., Birmingham, was the principal speaker before the Madison County Medical Society, April 10 on eczema.—Dr. Ernest W. Goodpasture, Nashville, Tenn., gave an address at the University of Alabama School of Medicine, University, April 28 on "A Medical Pageant."—Dr. David S. Moore, Jr., Birmingham, has been elected president of the Alumni Association of the University of Alabama Medical School.—The Tuscaloosa County Medical Society and the student body of the University of Alabama School of Medicine were addressed, April 21, by Drs. John J. Shea and Ralph E. Semmes, Memphis, Tenn., on "Management of Fractures of the Bones of the Face and Head and Brain Injuries," respectively. A joint meeting of the society and the medical staff of the Veterans Administration Faculty at Tuscaloosa, May 3, was devoted to presentation of cases. Included on the program were Drs. George L. Johnson, Herbert Caldwell, Joseph Rothman, George W. Kiehnhoff, James B. Berardi and Matthew T. Moorehead, Jr.

ARIZONA

State Medical Election—Dr. Nelson C. Bledsoe, Tucson, was installed as president of the Arizona State Medical Association at its annual meeting in Tucson, April 20. Dr. Fred G. Holmes, Phoenix, was named president-elect and Dr. Delamere F. Harbridge, Phoenix, reelected secretary. The next annual session will be held at Prescott in April, 1934.

ARKANSAS

State Medical Meeting and Election—At the annual meeting of the Arkansas Medical Society in Hot Springs National Park, May 2-4, Dr. Leonce J. Kosminsky, Texarkana, was installed as president, and Dr. Fergus O. Mahony, El Dorado, named president-elect. Other officers are Drs. Dewell Gann, Sr., Benton; James H. Fowler, Harrison, and John E. McGuire, Piggott, vice presidents, Dr. Royal J. Calcote, Little Rock, treasurer, reelected and Dr. William R. Bathurst, Little Rock, secretary, reelected. The program consisted of addresses by the following physicians, among others:

Dean Lewis, Baltimore: Diagnosis of Bone Tumors.
Everts A. Graham, St. Louis: Consideration of the Factors Influencing Mortality in Acute Empyema.
Darnon A. Rhinehart and William E. Gray, Jr., Little Rock: Importance of X-Ray Examination in Diagnosis of the Chest.
Jesse D. Riley, State Sanatorium, Antituberculosis Progress.
Herbert Fay H. Jones, Little Rock, Transurethral Prostatic Resection.
Charles S. Holt and Frederick H. Krock, Fort Smith: Tragedies of Surgery.
Herbert Moulton, Fort Smith: Phases of Vastoid Disease.
Robert Caldwell and Royal J. Calcote, Little Rock: Enucleation: Indications and Contraindications.
Lucian H. Lanier, Texarkana: Value of Correctly Fitted Glasses in Modern Ophthalmic Practice.
Lowry H. McDaniel, Tyrone: Observations on Pellagra.
Philip F. Barbour, Louisville, Ky.: Chorea.
Henry H. Turner, Oklahoma City: Hormones of the Anterior Pituitary.
Shelby B. Hinkle, Little Rock, Birth Injuries.
Grayson E. Tarkington, Hot Springs, Evaluation of the Swift Ellis Therapy in the Treatment of Neurosyphilis.

CALIFORNIA

Decrease in Infant Mortality Rate—There were 4,125 infant deaths in California in 1932 as compared with 4,609 in 1931, giving a rate of 52.8 per thousand live births as compared with an earlier rate of 56.5. Lower infant mortality rates prevailed among all races except Indian, Chinese and Japanese. The rate for white infants fell from 41.8 in 1931 to 40 in 1932. The death rate for Negro infants fell from 74.2 in 1931 to 58.6 in 1932. The rate among Mexican infants fell from 127.1 in 1931 to 118.9 in 1932. This decrease was probably influenced by the extensive migration of Mexicans to their mother country, the California department of health bulletin stated.

Lectures on Heart Disease—The prevention and relief of heart disease was the theme of an institute recently conducted in San Francisco by the San Francisco Heart Committee of the local county medical society. The lectures were arranged for public health nurses, physical education teachers and medical social service workers and were sponsored by the department of public health, the physical education department of the board of education and the Cardiac Center of the American Association of University Women. Speakers included Drs Walter H. Brown, on "Heart Disease a Public Health Problem," Clain F. Gelston, "Heart Disease in Infancy (Birth to Five Years)," John J. Sampson, "Prevention and Care of Heart Disease During Childhood and Adolescence (Six to Twenty Years)," and John P. Strickler, "Heart Disease in the Adult." The total attendance was about 1,000.

State Medical Meeting and Election—Dr. George G. Reimle, Oakland, was installed as president of the California Medical Association at the annual meeting, April 26. Dr. Clarence G. Toland, Los Angeles, was named president-elect and Dr. Emma W. Pope, San Francisco, was reelected secretary. The next annual session will be held at Riverside. Among the speakers on the program were the following physicians:

Ray Lyman Wilbur, Stanford University, Medicine at the Crossroads.
Arthur C. Christie, Washington, D. C., Significance to the Medical Profession of the Report of the Committee on the Costs of Medical Care.

Rosco G. Leland, director, Bureau of Medical Economics, American Medical Association, Chicago, New Forms of Medical Practice.
Cyrus C. Sturgis, Ann Arbor, Mich., Nature of Pernicious Anemia and a Consideration of Recent Advances in the Treatment of the Disease.

Harvey B. Stone, Baltimore, Living Grafts of Endocrine Glands.
Louis H. Maxson, Seattle, Spinal Anesthesia, Technique, Records and Results.

Gershom J. Thompson, Rochester, Minn., Surgical Treatment of the Prostate.

COLORADO

Changes in Faculty—The following changes in faculty at the University of Colorado School of Medicine, Denver, have been recently reported:

Dr. George S. Johnson, appointed as associate professor of psychiatry and neuropathology.

Dr. Paul H. Guttman, appointed as assistant professor of pathology.

Drs. Ralph W. Danielson and Maurice E. Matcove, appointed instructors in ophthalmology.

Dr. Ora L. Huddleson, appointed instructor in physiology and pharmacology.

Dr. Enid K. Rutledge, appointed instructor in pathology.

Dr. John B. Davis, resigned as associate professor of surgery (urology).

Dr. William C. Finnoff, resigned as associate professor of ophthalmology.

CONNECTICUT

Bill Introduced—A substitute for H. 502 proposes to authorize the state department of health instead of the governor, to license annually institutions for the treatment or detention of insane persons or persons suffering from other abnormal mental or nervous conditions. The department is to be authorized to prescribe a sanitary code for the government of such institutions and to revoke licenses for stated causes.

DELAWARE

Society News—Dr. George E. Pfahler, Philadelphia, addressed the New Castle County Medical Society at Wilmington, April 18, on "Irradiation Treatment of Uterine Tumors." Case reports were given by Drs. Louis S. Parsons, Wilmington, and Edgar R. Miller, Richardson Park, on "Congenital Occlusion of the Common Bile Duct" and "Undulant Fever," respectively. Dr. Wilmer Krusen, Philadelphia, delivered a public lecture, April 21, on "Pharmacy and the Public." C. J. Hollister, DDS, chief dental division, Pennsylvania State Department of Health, gave a public address, April 26, on "Effect of Teeth on the Future of Our Country." These lectures were under the auspices of the Delaware Academy of Medicine.

DISTRICT OF COLUMBIA

Society News—Speakers before the Medical Society of the District of Columbia, March 29, were Drs. William Calhoun Stirling, Jr., on "Recurrent Cancer of the Prostate Unrelieved by Prostatectomy Treated by Transurethral Resection," and Richard A. Kearny, "Observations and Considerations on the Diagnosis and Treatment of Mastoiditis."—Dr. Wallace M. Yater addressed the District of Columbia Dental Society, March 28, on "How Much of a Physician Should a Dentist Be?" and "Fundamentals of Heart Disease." George R. Ellis, DDS, spoke on "Relation of General Dentistry to Systemic Diseases." Boyd S. Gardner, DDS, Rochester, Minn., addressed a joint meeting of the society with the Medical Society of the District of Columbia, March 22, on the relationship between medicine and dentistry.

District Election—Dr. Prentiss Willson, Washington, was elected president of the Medical Society of the District of Columbia at its annual session, May 3, to serve from July, 1933, to June 30, 1934. Vice presidents are Drs. Daniel Leray, Borden and Margaret Mary Nicholson. Dr. Coursen B. Conklin, Washington, was reelected secretary. Included among the speakers on the program were Drs. Leonard G. Rowntree, director, Philadelphia Institute for Medical Research, Philadelphia, on "Recent Advances in Diseases of the Endocrine Glands," and Maude E. Abbott, curator of Medical Museum, McGill University, Montreal, "Personal Reminiscences of Osler and Remarks on His Contribution to Our Knowledge of Heart Disease." Dr. Dean Lewis, Baltimore, President-elect, American Medical Association, addressed a public meeting, April 26, on "Changing Times in Medicine."

FLORIDA

Bills Introduced—S. 471, to amend the laws regulating the possession and distribution of narcotic drugs, proposes (1) to prohibit the possession of any narcotic drug or cannabis indica except on the written prescription of a duly licensed physician, dentist or veterinarian, (2) to make a violation of the act a felony, punishable by one year in prison and a fine of not less than \$1,000, or both, and (3) to make it the duty of the state board of health and of all peace officers to enforce the provisions of the act. H. 1070 proposes to forbid the selling at retail of marihuana, marijuana, cannabis indica, hashish, gangah, gringah, bhang, loco weed, or any compounds containing cannabene, cannabinol or lacome except by a licensed druggist on the written prescription of a licensed physician or dentist.

GEORGIA

State Medical Election—Dr. Clarence L. Ayers, Toccoa, was named president-elect of the Medical Association of Georgia at the close of the annual meeting in Macon. Dr. Charles H. Richardson, Jr., Macon, was installed as president and the following were elected vice presidents: Drs. Joseph D. Applewhite, Macon, and William W. Turner, Jr., Nashville. The 1934 session will be held in Augusta.

ILLINOIS

State Medical Election—Dr. Charles D. Center, Quincy, was chosen president-elect of the Illinois State Medical Society at the annual meeting in Peoria, May 18, and Dr. Philip H. Kreuscher, Chicago, became president. Vice presidents elected were Drs. Charles G. Farnum, Peoria, and Harold V. Gould, Chicago. Dr. Harold M. Camp, Monmouth, was reelected secretary. The society will meet in Springfield in 1934.

Dr. Ascher Elected Mayor—Dr. John A. Ascher was elected mayor of Freeport, April 4, and he assumed office, May 1. Dr. Ascher, who is a member of the board of censors of the Stephenson County Medical Society, was president of the society in 1926. In Sparks, Nev., where he practiced for several years, Dr. Ascher served at different times as city and county health officer.

Campaign Against Diphtheria—A house to house canvass throughout Decatur is part of a special campaign against diphtheria being carried on under the auspices of the community health council and the city health officer, the Illinois Health Messenger reports. A chairman and twenty or more workers for each of twenty-five districts were recruited from volunteers in parent-teacher associations. Each worker was assigned a definite area. Every home is visited and a record obtained of all children under 16 years of age. Literature on diphtheria prevention is left with the parents. For persons unable to pay, special clinics are being held the first of which was scheduled, April 15. In addition to the canvass, illustrated lectures were given in various parts of the city.

Chicago

Case Nolle Prossed—The case of Dr. Anthony M. Catania, who had been indicted by the grand jury, Dec. 28, 1932, on a charge of murder by abortion, was nolle prossed by the state's attorney when it was called for trial in criminal court, March 23. Dr. Catania graduated in 1930 from Loyola University School of Medicine and was licensed in Illinois the same year.

Personal—Dr. Ernest E. Irons, dean, Rush Medical College, has been appointed chairman of the department of medicine succeeding Dr. George F. Dick. Dr. Dick continues as professor in the department of medicine at the college and as professor and chairman of the department of medicine in the Division of Biological Sciences, University of Chicago. — Dr. William P. MacCracken, senior medical examiner for the aeronautics branch of the U. S. Department of Commerce in

this area, has been appointed medical director of the American Air Races to be held at the Chicago airport, July 1-4

Society News—"Influence of the Pituitary Gland on Metabolism" was discussed at the meeting of the recently organized Endocrine Club, April 18, speakers were Dr Hugo R. Rony and Broda O Barnes Ph.D.—Dr Arthur C Christie, Washington, D C addressed the Chicago Roentgen Society, April 20, on 'Relation of the Medical Profession to the Costs of Medical Care'—Dr Janet S Barnes Ann Arbor addressed the Chicago Council of Medical Women May 5, on "Problem Parents of the So Called Problem Children"—Speakers before the Chicago Pathological Society May 8 included Drs Victor Levine on Chronic Embolism of the Lungs", William R Williams Riverside Ill., Experimental Studies of the Effects of Lung Compression on the Pulmonary Circulation, and Perry J Melnick Theca Cell Tumors of the Ovary—Dr Edward A Bullard New York, among others, addressed the Chicago Gynecological Society, May 19, on "Cervicitis and Its Operative Treatment"

INDIANA

Society News—At a meeting of the Fifth District Medical Society in Terre Haute May 5 poliomyelitis was discussed by Drs William H Allen Virgil E Simpson James H Pritchett and Frank P Strickler, all of Louisville, Ky—Dr Joseph H Weinsteim Terre Haute talked on medical economics before the Bartholomew County Medical Society at Columbus, May 3—The Tippecanoe County Medical Society was addressed by Dr John Sundwall Ann Arbor, Mich., on 'Social Trends in Medical Practice' and Critical Age of Forty—Dr Granville S Hanes Louisville conducted a rectal clinic before the Ripley County Medical Society in Osgood May 10—A symposium on the education of the public in medical matters was presented before the Indianapolis Medical Society May 16, the speakers were Drs Thurman B Rice, James H Stygall John A MacDonald and William N Wishard, Sr—Dr Olin West Chicago secretary and general manager of the American Medical Association addressed the St. Joseph County Medical Society in South Bend, April 26, on medical economics

IOWA

Society News—Dr Benjamin F Wolverton Cedar Rapids, was elected president of the Iowa Clinical Medical Society at its spring meeting April 13—Dr Augustus G Pohlman, Vermilion, addressed the section on ophthalmology of the Des Moines Academy of Medicine and the Polk County Medical Society, April 17, on 'Difference Between the Visualized and Audiotized Interpretations of the Hearing Apparatus and Their Relation to the Prevention and Treatment of Deafness'

Inter-Professional Association.—The O'Brien County Inter-Professional Association was recently organized according to the *Journal of the Iowa State Medical Society*, to protect the public health from jeopardy by unskilled, poorly trained and otherwise incompetent persons. The new organization will also concern itself with all public health problems, including vaccination for contagious diseases prevention and control of epidemics, and testing of milk cattle herds. Membership comprises fifty-five physicians, dentists druggists, veterinarians and nurses. The society will meet quarterly

KENTUCKY

Society News—Drs Emmet F Horne and Morris M Weiss addressed the Jefferson County Medical Society, Louisville May 15, on 'Etiological Incidence of Heart Disease in Kentucky'—Dr Max Cutler Chicago addressed the society, April 17, on Relation of Chronic Mastitis, Cysts and Papilloma to Carcinoma of the Breast. Demonstration of Tumors of the Breast by Transillumination—Dr L Wallace Frank Louisville, addressed the Christian County Medical Society, Hopkinsville March 21, on cancer of the breast.

MAINE

Society News—At a meeting of the Androscoggin Medical Society, April 14 Dr George E Young, Skowhegan, gave an illustrated address on chest surgery and surgical treatment of tuberculosis of the lungs—The Cumberland County Medical Society was recently addressed by Dr Eric M Matsner New York on 'Technic of Contraception'—Dr Thomas A Foster discussed "Rheumatic Fever before the Portland Medical Club April 4—A recent meeting of the Penobscot County Medical Association was addressed by Drs Harry Butler and Magnus F Ridlon Bangor among others, on 'Sinus Disease and General Diagnosis and 'Dehydration Treatment of Eclampsia' respectively

MASSACHUSETTS

Society News—Dr Zabdriel B Adams Boston, addressed the New England Roentgen Ray Society, April 21, on "Early Appearance and End-Results of Skeletal Tuberculosis"—Among others Dr Alice Ettlinger Berlin, Germany, addressed a joint meeting of the Greater Boston Medical Society and the Beth Israel Hospital, April 18, on "X-Ray Studies of the Gastro-Intestinal Mucosa Diagnostic Value."—Dr Howard W Haggard New Haven, Conn, addressed the Worcester District Medical Society in Rutland April 12 on 'Charlatanism'—At a meeting of the South End Medical Club in Boston April 18, Dr William P Boardman spoke on syphilis

Public Health Lectures—An institute of public health was begun in Roxbury April 24 under the auspices of the Boston Health Department. On this day Drs Wilson G Smilie spoke on 'The Physician and Public Health' Thomas R Goethals Obstetrics Prenatal Care," and Alonzo K. Paine Delivery and Postpartum Care." Subsequent lectures were as follows

Drs Richard M Smith and Harold C. Stuart The Infant and Child Normal Development Health Supervision Prevention of Disease April 26 and 28

Dr Edwin H Place Methods for the Control of Specific Diseases May 1

Dr Cleaveland Floyd Prevention and Control of Tuberculosis May 1

Dr William H Robey Extension of Preventive Measures in Adult Life May 3

Clair E. Turner Dr P H Health Education May 5

Dr Charles F Wilensky Relationships Between Health Departments and the Medical Profession May 5

MICHIGAN

Bills Introduced—H 580, to amend the narcotic drug act proposes to eliminate the provision which requires that exempted preparations of narcotic drugs contain some drug adapted in quantity and quality to prevent the use of the exempted preparation for gratification of narcotic addiction H 622 to amend the workmen's compensation act, proposes to increase from 90 to 180 days the period after an industrial injury during which an employer must furnish medical surgical and hospital services and medicines to an injured employee

Report on Survey of Michigan Medical and Health Agencies—The secretary of the Michigan State Medical Society, Dr Frederick C Warnshuis, Grand Rapids, informs THE JOURNAL that a complete report of the great survey of medical and health agencies in the state of Michigan which has been in process of development for more than a year will be available early in June. The report is exceedingly comprehensive and includes some thirty pages of summary and forty pages of conclusions. Those who desire a copy of this report may secure one by writing directly to the Secretary of the Michigan State Medical Society, the cost of the publication being \$2.50 per copy. There are to be 250 pages in the report exclusive of tables maps and charts

Plan to Care for Middle Class—Complete diagnostic facilities will be available to every worthy patient at a cost directly proportionate to his ability to pay, through a plan evolved by the Wayne County Medical Society to provide medical care for the middle class. In addition, the project offers the advantages of a well organized type of group practice free choice of physician and the preservation of the present fundamentals of medical practice. The society will become an active staff caring for patients in this class its headquarters serving as a coordinating center for those who need but cannot afford complete diagnostic service at customary rates. Forms will be used to determine the percentage ability to pay, so that an equitable basis may be furnished each physician, x-ray or clinical laboratory to make charges. Patients who apply at the headquarters are to be referred to a general practitioner or family physician listed in a directory made up of the society's members

MISSOURI

Trudeau Lecture—Dr Allen Krause, Tucson, Ariz, gave the annual Trudeau Lecture before a joint meeting of the St. Louis Trudeau Club and the St. Louis Medical Society April 25. His subject was "The Principles of Activity in Pulmonary Tuberculosis." The lecture is sponsored by the Trudeau Club

Gift to Medical School—Presentation of 1,250 copies of THE JOURNAL was recently made to Washington University School of Medicine St. Louis by Dr Charles S Austin Carrollton an alumnus. In addition to these journals, which date from 1909 a number of old medical volumes, going as far back as 1838 were included. The latter were a part of the medical library of Dr Austin's grandfather, Dr John S Williams said to have been the first physician to locate in Chillicothe

Library in New Quarters—The library of the Jackson County Medical Society has been moved from the Medical Arts Building in Kansas City to the second floor of the Kansas City General Hospital. The nucleus of the library, which was assembled by the Kansas City Medical Club, consisted of books and journals belonging to Dr Arthur E Hertzler. In 1921, the Jackson County Medical Society took over the library. From its inception in 1911 to 1921, the library was housed in the Rialto Building from 1921 to 1925 it occupied quarters at the Kansas City General Hospital and from 1929 through 1932 it was in the Medical Arts Building. In 1932, 7,562 persons used the library, as compared with 897 in 1914.

NEBRASKA

Change in State Health Department—Under new legislation effective April 1, the State of Nebraska Department of Health replaced the former Department of Public Welfare. Dr Philip H Bartholomew is now director of health.

Society News—Members of the staff of University Hospital presented the program of the Omaha-Douglas County Medical Society, Omaha, April 11, as follows: Drs Manuel Grodinsky, "Experimental and Clinical Studies of Spinal Anesthesia", Alfred J Brown "Pentacaine as a Spinal Anesthetic", Olin J Cameron "Self-Induced Lesions of Skin," and Ernest L MacQuiddy, "Air Conditioning".—Drs John C Thompson and Clarence C Hickman, Lincoln addressed the March meeting of the Otoe County Medical Society, Nebraska City, on "Arthritis with Reference to Treatment with Crowe's Vaccine" and "Tumors of the Colon with Special Reference to Multiple Polyposis," respectively.

NEW HAMPSHIRE

Personal—At a recent special election, Dr George W Nutter, Salmon Falls who is 75 years old was elected representative to the state legislature, succeeding the late Gardner Grant. Dr Nutter has served four previous terms in the legislature.

Society News—At a recent meeting of the Carroll County Medical Society in Wolfeboro, Drs John S Wheeler Wolfeboro, and Harry O Chesley, Dover president of the state medical society spoke on "Complications of Influenza" and "Problems of Organized Medicine," respectively. Motion pictures on "Traumatic Surgery of the Extremities" were also shown at this meeting.

NEW YORK

Care of the Indigent in Buffalo—Under a plan recently evolved by the committee on medical economics of the Erie County Medical Society and representatives of the hospitals and social agencies of Buffalo, free or part pay clinics investigate the financial status of those who apply for treatment and refer them back to private physicians. The physicians may then accept them as free or part pay patients or send them back to the clinic. In acute conditions, treatment will be given immediately however.

Typhoid Carriers in 1932—Six hundred and twenty typhoid carriers were registered by the New York State and New York City departments of health at the end of 1932 an increase of 61 over the previous year. Of this number 311 were in New York City, 290 in the state outside New York City, and 19 in state institutions. Only eight carriers who were under supervision of the state health department Jan 1 1932, are known to have caused cases in 1932. Of twenty cases traced to these carriers eleven are known to be due to one carrier who handled food at a party despite the fact that she had been warned of the danger of infecting other persons.

New York City

Hospital News—Alumni Day was observed at the Hospital for Joint Diseases, May 3. Operative clinics were held in the morning followed by demonstrations of the use of filtered ultra-violet radiation in the operating room and pathologic specimens of intervertebral disks and sacro-iliac joints. A dry clinic was held in the afternoon, after which Dr Emanuel Libman presented a paper on "Diagnostic Observations on Some Abdominal Diseases" and Dr Edgar M Bick on "Present Trends in Orthopedic Surgery in Light of Its Past History."

Columbia University News—Columbia University College of Physicians and Surgeons has announced the appointment of Howard B Adelman PhD, as assistant professor of anatomy. Dr Richard F Thompson assistant professor of bacteriology, and Dr Karl Meyer, assistant professor of biologic chemistry. Dr Meyer received his medical degree at the University of Cologne, Germany, and has recently been at the University of California.—The alumni association of the

college held its annual dinner, March 29, in Bard Hall, with Dr Bern B Gallaudet, associate professor of anatomy, as guest of honor.—A fund to establish the Herbert Swift Carter Lectureship in Diseases of the Digestive Tract has been set aside to commemorate the life and work of the late Dr Carter, for many years a member of the Columbia faculty.

Honorary Fellows Elected—Thirteen physicians and research workers have recently been elected to honorary fellowship in the New York Academy of Medicine, as follows:

Dr James B Herrick, emeritus professor of medicine Rush Medical College Chicago
Dr George R Minot professor of medicine Harvard University Medical School Boston
Dr William Gibson Spiller professor of neurology University of Pennsylvania School of Medicine Philadelphia
Dr Frederick G Banting professor of medical research University of Toronto Ontario
Prof Charles Achard Faculté de médecine Paris
Dr Roberto Alessandri director of surgical clinic, University of Rome.
Sir Charles Ballance consulting physician St. Thomas Hospital National Hospital for Paralysis and Epilepsy London
Sir Henry H Dale director National Institute for Medical Research London
Otto Foerster professor of psychiatry and neurology University of Breslau Germany
Carl Gustaf Forssell professor of radiology Medico-Chirurgical Institute Stockholm Sweden
Cornelius Ubbo Ariens Kappers professor of comparative anatomy of the nervous system University of Amsterdam.
Alfred Vogt professor of ophthalmology University of Zurich Switzerland.
Karel Frederic Wenckebach, for many years professor of medical pathology and therapy University of Vienna.

NORTH CAROLINA

State Medical Election—Dr Paul P McCam Sana torium, was chosen president-elect of the North Carolina State Medical Society at the annual meeting in Raleigh in April. Dr Isaac H Manning Chapel Hill, was installed as president. At a joint meeting of the society with the state board of health, Drs William T Rainey, Fayetteville, and Sylvester D Craig Winston-Salem, were elected to the board. Pinehurst was designated as the place for the next annual session, May 30 June 2, 1934. Dr L B McBrayer, Southern Pines, is secretary of the society.

OHIO

Personal—Dr and Mrs Charles Huber, Harrison, celebrated their golden wedding anniversary, April 17.—Dr J Eugene Baker, Marion, was recently guest of honor at a special meeting conducted by his Sunday school class celebrating his fiftieth anniversary in the practice of medicine. Members of the Marion Academy of Medicine were guests.—Dr Jerome Gross Cleveland, gave a violin recital in the auditorium of the Cleveland Medical Library May 2.—Dr Aaron H Smith recently assumed the superintendency of Pleasant View Sanatorium Amherst.—Dr Emerson Paul Shepard, formerly of Columbus, has been named president of the American Medical Association in Vienna, according to the Quincy (Ill.) Medical Bulletin. Dr Shepard is studying in Vienna.

Appointments at Cincinnati—The board of trustees of the University of Cincinnati School of Medicine recently announced the following appointments and promotions:

Dr Emerson A. North professor and head of the department of psychiatry
Dr Frank M. Coppock Jr. head of the department of gynecology
Dr Maurice Levine assistant professor of psychiatry
Dr Gustav Eckstein Jr. assistant professor of physiology
Dr Franz H. Miketta associate professor in obstetrics
Drs Daniel J. Davies and Robert L. Crudginton assistant professors of obstetrics
Dr Helena T. Ratterman assistant clinical professor
Drs Thaddeus R. Gillespie and William P. Gillespie instructors in obstetrics
Dr James M. Pierce instructor in obstetrics.
Drs Lloyd B. Johnston and Francis M. Oxley instructor in clinical surgery
Dr Jean M. Stevenson assistant in surgery

PENNSYLVANIA

Society News—Drs Bernard J McCloskey and Horace B Anderson Johnstown, addressed the Cambria County Medical Society, May 11, on heart disease and Lycurgus M Gurley, Johnstown presented a review of research in ophthalmology.—Drs John P Harley and Charles L Youngman Williamsport discussed medical economics and blood transfusion, respectively, at a meeting of the Tioga County Medical Society, April 21.—Dr Norris W Vaux Philadelphia, was the speaker at a meeting of the Delaware County Medical Society, Chester, May 11 on advances in teaching and practice of obstetrics. At a joint meeting with the dentists of Delaware County in March the society heard addresses by Dr Chevalier Jackson, on "Bronchoscopic and Esophagoscopy Cases of

Interest, James R. Cameron DDS cooperation between medicine and dentistry, Dr Seth A. Brumm, the economic situation in medicine, and E. Fullerton Cooke Pharm D, public health service of the pharmacist. All were from Philadelphia. —Dr Ralph M. Tyson, Philadelphia addressed the Dauphin County Medical Society Harrisburg May 2 on preventive pediatrics for the general practitioner. —Dr Adam C. Williamson, Pittsburgh addressed the Washington County Medical Society, Washington, May 10 on Temperatures and Complications of the Puerperium. —Dr Wallace S. Duncan Cleveland addressed the Fayette County Medical Society, May 4 on 'Post-Traumatic Back Pain in Relation to Compensation.' —Drs Hubert A. Royster, Raleigh N. C. and William D. Reid, Boston, were guests of the Lycoming County Medical Society at its annual spring clinic meeting at Williamsport May 12. Dr Reid discussed diagnosis and prognosis of heart disease and Dr Royster various aspects of appendicitis.

Philadelphia

Society News—Dr Max M. Strumia among others addressed the Pathological Society of Philadelphia, May 11 on 'Agranulocytosis and Acute Leukemia.' —Drs Samuel Goldberg and Nathan M. Levin among others, addressed the Philadelphia Pediatric Society May 9, on 'Pediatric Studies of Pulmonary Suppuration and Foreign Bodies.'

Portrait Presented to Jefferson—The class of 1933 at Jefferson Medical College presented to the college a portrait of the late Dr Elmer H. Funk, who was professor of therapeutics. Dr Thomas McCrae made the presentation on behalf of the class, April 6 and the portrait was accepted by Alba B. Johnson, chairman of the board of trustees. Dr Funk was medical director of Jefferson Hospital during the absence of Dr Henry K. Mohler in war service and later became professor of diseases of the chest.

Demonstrations on Heart Disease—The Philadelphia Heart Association presented intensive demonstrations of the latest methods of diagnosis and treatment of heart disease, May 15-18. About thirty-five physicians participated in the demonstrations, which were held at Pennsylvania Hospital Temple University Medical School Hospital and the Medical Clinic of the University of Pennsylvania, Jefferson Medical College Hospital, the pathology laboratory of the University of Pennsylvania School of Medicine and the Philadelphia General Hospital.

RHODE ISLAND

State Medical Meeting, June 1—The annual meeting of the Rhode Island Medical Society will be held in Providence June 1, under the presidency of Dr Norman Darrell Harvey, Providence. The program is as follows:

Dr Lyman G. Richards Boston Acute Tracheobronchitis in Children.
Dr Max J. Exner New York Congenital Syphilis.
Dr Ralph Pemberton Philadelphia Arthritis.
Dr Henry W. Hudson Jr Boston Abdominal Emergencies in Infancy and Childhood.
Dr Marshall N. Fulton Boston Use of Diuretics in the Treatment of Renal and Cardiac Eczema.
Dr Clifton B. Leech Providence Complete Heart Block in Young People.
Dr Frederic V. Hussey Providence Surgical Risks and Postoperative Complications of Diseases of the Biliary Tract.
Dr Harold F. Corson Providence, Diagnosis and Treatment of Children Thought to Have Epilepsy.

The annual dinner will be held at the Squantum Club with Richard Washburn Child, Newport, former ambassador to Italy, as speaker.

SOUTH DAKOTA

Society News—The Aberdeen District Medical Society held its quarterly meeting, April 11 with the following speakers on the program: Drs Nelson W. Barker, Rochester Minn. on 'Differential Diagnosis and Treatment of Vascular Diseases of the Extremities,' Carl W. Forsberg Sioux Falls, Practical Laboratory Tests and Their Interpretation, and Maksymilian R. Gelber, Britton, Avertin and Spinal Anesthesia. —Dr Oliver J. Fay, Des Moines, Iowa, addressed the Yankton District Medical Society Vermillion April 28 on the reports of the Committee on the Costs of Medical Care.

TEXAS

Public Health Forum in Fort Worth—The Tarrant County Medical Society during the past year established an open forum for the public for the discussion of physical and mental hygiene. Meetings are held weekly at the auditorium of the society, and the interest has grown so that the hall is inadequate, according to a report in the *Texas State Journal of Medicine*. A member of the society makes a talk each week and allows time for questions and answers. Among speakers

have been Drs Arthur H. Flicker, on rabies, Edwin G. Schwarz, prevention of infectious diseases in children, Marquis E. Gilmore blood pressure, William S. Barcus, diabetes, and Jack McLean acute abdominal conditions.

Society News—Drs James H. Black and Julia Florence Widney Austin, Dallas, among others, addressed the Dallas County Medical Society, April 13 on 'Blood Sugar in Allergic Persons' and 'High Blood Pressure and Hypothyroidism,' respectively. Among speakers at the meeting were Drs Curtice Rosser and George T. Caldwell Dallas on 'Venereal Diseases Affecting the Rectum' and 'Neoplasms of Reticulo-Endothelial Origin' respectively. —The Texas Club of Internists held its spring meeting in Fort Worth, March 3-4, with Dr Allen K. Krause, Tucson, Ariz., as guest. Dr Krause made an address on 'Tuberculosis a Generalized Infection.' Dr William E. Nesbit San Antonio, was elected president. —The Northwest Texas District Medical Society met in Mineral Wells, March 7, among speakers were Drs Everett C. Fox, Dallas, on 'Treatment of Skin Cancer' and Arthur C. Scott Temple, 'What the Public Should Know About Cancer.' —Dr Roy L. Vineyard Amarillo, was chosen president elect of the Panhandle District Medical Society at its spring meeting in Amarillo, April 12. Among the speakers were Drs Alfred I. Folsom, Dallas, on prostatic resection, Thomas E. Carmody, Denver, sinus infections and Albert O. Singleton, Galveston, surgery of the heart. The fall meeting will be held in Plainview.

VIRGINIA

Society News—Dr Harold L. Amoss, Durham N. C. was the guest speaker at the annual all day clinic of the Norfolk County Medical Society Norfolk, April 12. Dr Amos spoke on 'Treatment of Streptococcal Pneumonia.' —Drs Samuel J. Kopetzky, New York, and Thomas D. Allen, Chicago, addressed the Virginia Society of Otolaryngology and Ophthalmology at the annual meeting in Harrisonburg, May 6, on 'Problems Concerned with Petrositis' and 'Dissecting Blebs Following Fistulization Operations,' respectively.

University News—Courses will be offered at the University of Virginia department of medicine, June 19-July 29, in histology, embryology, anatomy, biochemistry, physiology, medical bacteriology, pathology, pharmacology and mental hygiene. —Clinics in pediatrics, obstetrics, surgery and medicine were presented for practicing physicians, March 22-23, at the Medical College of Virginia, Richmond. Instructors were Drs Samuel A. Anderson, Jr., Lee E. Sutton, Jr., Fred J. Wampler, Harry H. Ware, Jr., Greer Baughman, Isaac A. Bigger, Donald M. Faulkner, George Paul La Roque, Claude C. Coleman, Manfred Call, James H. Smith, William A. Shepherd, William H. Higgins and James M. Hutcheson.

WASHINGTON

Personal—Dr Albert E. Stuht, Seattle, has resigned as state health commissioner of the Washington State Board of Health after serving for eight years. Dr Austin U. Simpson, assistant director of health will be in charge of the department until a new director has been appointed.

WEST VIRGINIA

Bill Passed—H. 98 has passed the house, proposing to require the physical examination of all children at the time they enter public or private schools for the first time to determine the presence of communicable diseases or defects. Children found suffering from any communicable disease in an acute or infectious stage are to be barred from school.

Acting Health Commissioner Appointed—Dr David Littlejohn, director of rural sanitation in the state health department since 1927, has been appointed acting head of the department to succeed Dr William T. Henshaw, resigned. Dr Littlejohn served as health officer of Bluefield for several years and had previously been health officer of various towns in the Middle West. He is president of the West Virginia Public Health Association.

Society News—Dr Stuart McGuire, Richmond, addressed the Kanawha Medical Society, Charleston April 11, on 'Cancer of the Breast.' —A meeting of the Wyoming County Medical Society Mullens March 28, was devoted to discussion of the West Virginia compensation law. —At a joint meeting of the Cabell County Medical Society and the Parkersburg Academy of Medicine in Huntington April 13, Drs Oliver D. Barker and William R. Goff, Parkersburg, discussed urologic cases and hypothyroidism. —Dr Harry McGrath, Montgomery, addressed the Fayette County Medical Society, Montgomery, April 12 on 'Relation of the Paranasal Sinuses to Systemic Disease.' —At the quarterly meeting of the Central Tri-State

Medical Society, Huntington, May 18 speakers were Drs Philip T. Barbour, Louisville, Ky., on 'The Cost of Medical Care', Clyde M. Fitch, Portsmouth, Ohio, 'Effectiveness of Mercury as a Diuretic', Wade H. St. Clair, Bluefield, 'Review of Gallbladder Surgery', William A. MacMillan, Charleston, W. Va., 'Intestinal Obstruction' and William S. Fulton, Wheeling, W. Va., 'The Hundredth Case'—Dr P. Brooke Bland, Philadelphia, addressed the Ohio County Medical Society, Wheeling, April 28 on "Prevention of Maternal Mortality from Puerperal Hemorrhage."

WISCONSIN

Bill Introduced—Substitute Amendment No. 1 to A 589 proposes to create a board of chiropractic examiners and to regulate the practice of chiropractic. Licentiatees are to be permitted to practice "chiropractic" which the bill does not define, to make and sign birth and death certificates, to render the medical care which employers are required under the workmen's compensation act to furnish their injured employees and to use the title 'doctor' if the designation 'doctor of chiropractic' or the abbreviation 'D. C.' appears following the name of the licensee.

WYOMING

County Health Officers—The state board of health, the *Casper Herald* reports has recently assigned county health officers as follows:

Albany Dr. Richard M. Leake.	Natrona Dr. Joseph C. Kamp
Big Horn Dr. Stanley I. Myre.	Niobrara Dr. Guy D. Murphy
Campbell, Dr. J. C. McHenry	Park Dr. Frances M. Lane
Carbon Dr. Charles W. Jeffrey	Platte, Dr. Charles E. Fish
Converse Dr. Joseph R. Hyton	Sheridan Dr. E. E. Whedon
Crook, Dr. John L. Bostwick	Sublette Dr. John W. Montrose
Fremont Dr. Paul R. Holtz	Sweetwater Dr. E. S. Lauzer
Goshen Dr. Orville C. Reed	Teton Dr. Charles W. Huff
Hot Springs Dr. Robert W. Hale	Uinta Dr. Josiah H. Holland
Johnson Dr. Walter J. Knebel	Washakie Dr. Paul S. Read
Laramie Dr. George M. Anderson	Weston Dr. Fred Horton
Lincoln Dr. John R. Newnam	

GENERAL

Decrease in Smallpox.—Comparison of the number of cases of smallpox reported for the years 1928 to 1932 inclusive, shows the most notable decrease of any disease reported to the U. S. Public Health Service in that period. In 1932 there were 11,168 cases, compared with 39,396 in 1928. Figures for the intervening years are 1929, 42,282, 1930, 48,907, and 1931, 30,232.

Medical Information During Century of Progress.—The committee of the Chicago Medical Society for the Century of Progress is arranging a booklet on medical information about Chicago, which will include a list of fixed clinics in hospitals and medical schools. The committee will supply visiting physicians with information at its bureau of information and booth, K-15 ramp, in the Hall of Science. The wives and daughters of physicians will also be assisted at this booth by the woman's auxiliary of the Chicago Medical Society. Dr. Hugh N. MacKechnie is chairman of the committee.

Hotel Physicians Organize.—A number of physicians associated with large hotels in Chicago recently organized the Hotel Physicians Association of America with the following officers: Dr. Maurice W. Samuels, president; Lee H. Kiel, vice president, and Joseph N. Blake, secretary. All of Chicago. Purposes of the association are to raise and maintain the standard of practice in hotels, to protect the health and welfare of the traveling public, to establish a medium of exchange of information among hotel physicians and to keep unethical practitioners out of hotels. It is planned to extend the organization gradually to hotel physicians throughout the country. Applicants for membership must be graduates of class A schools of medicine and members of the American Medical Association in good standing.

Delegates to Congress on Military Medicine.—The U. S. Department of State announces that at the invitation of the Spanish government delegates to the Seventh International Congress of Military Medicine and Pharmacy at Madrid May 29-June 4 will be as follows:

Dr. John McMullen of the U. S. Public Health Service now stationed in Paris.
Col. Harold D. Corbuser, Medical Reserve U. S. Army, Plainfield N. J.
Lieut. Col. Francis E. Fronczak, Medical Reserve U. S. Army, Buffalo.
Commander William Seaman Bainbridge, Medical Reserve U. S. Navy.
Major Edgar E. Hume, Medical Corps U. S. Army, Army Medical Museum, Washington, D. C.
Lieut. Com. Julius F. Neuberger, U. S. Naval Hospital, Newport R. I.

Medical Director McMullen and Lieutenant Commander Neuberger will represent the United States at the International Congress on Sanitary Aviation, to be held concurrently.

News of Epidemics.—An outbreak of forty-three cases of smallpox was reported from Lowellville, Ohio, during March. About 1,500 persons were vaccinated.—A case of smallpox in a visitor to Barney, Ga., in March resulted in wholesale vaccination of citizens of Quitman and Brooks counties.—An outbreak of typhoid at Banner Lick, N. C., in April, was traced to a contaminated water supply.—Mumps was reported to be epidemic in Waterloo, Iowa. 119 cases having been noted during March.—Seven rural schools were closed and public gatherings were banned in several townships in Portage County, Ohio because of a serious outbreak of scarlet fever in March and April. Epidemics were also recently reported from Akron, Ohio, Alpena, Mich., and Arlington, Wis.—In Toledo, Ohio, 1,172 cases of measles were reported between April 1 and 24. In Dallas, Texas, 529 new cases were reported during the last week of March.—Six cases of diphtheria with one death, were reported from the village of San Mateo, N. M., April 10.

Impostor Uses Physicians' Names.—Dr. Paul K. Shirk, Yonkers, N. Y., reports the activities of a man who is obtaining money pretending to be a physician. He appeared at Dr. Shirk's office, March 15, claiming to be Dr. Malachi W. Sloan, Jr. and giving his address as Tyrone, Pa., and the name of Dr. William Hermanutz, supposedly also of Tyrone, as reference. Investigation revealed that Dr. Sloan and Dr. Hermanutz do not live in Tyrone. About April 1 the same man appeared at Jefferson Medical College, Philadelphia, calling himself Dr. Sloan and using the names of Dr. Edward J. Wagner, New York, and Dr. Shirk as references to borrow money from a student. The impostor is said to be about 25 years old, 5 feet 6 inches tall, and clean shaven with light brown hair and gray or blue eyes. According to Dr. Shirk, he dresses cheaply and his grammar is poor. He claims however to be a graduate of Northwestern University Medical College, Chicago. He appears to know many Jefferson graduates and has sufficient knowledge of medical phraseology to carry him through a general conversation.

Society News.—The American Laryngological, Rhinological and Otological Society will hold its annual meeting in Chicago June 8-10 at the Lake Shore Athletic Club under the presidency of Dr. Joseph C. Beck, Chicago. Members of the medical profession are cordially invited to attend. For all other information write Miss Margaret Wolf, Room 2009, 25 East Washington Street, Chicago. Telephone Randolph 0244.—The American College of Physicians announces that its eighteenth annual clinical session will be held in Chicago April 16-20, 1934. Mr. C. R. Loveland, executive secretary, 133-135 South Thirty-Sixth Street, Philadelphia, is in charge of general arrangements.—The National Research Council recently awarded eighteen fellowships in medicine for study in the United States and Europe. Applications to be placed before the fall meeting of the Medical Fellowship Board should be filed with the Washington office before August 1.—The Great Northern Railway Surgeons Association will hold its annual meeting in Portland, Ore., June 19-20. Speakers will include Drs. Charles W. Burns, Winnipeg, Man., on "Traumatic Rupture of Spleen", Paul O. Neraal, Cut Bank, Mont., Treatment of Supracondylar Fractures of the Humerus" and Roscoe C. Webb, Minneapolis, 'Application of First Aid Splints to Fractures of the Upper and Lower Extremity'.

Sectional Meetings on Physical Therapy.—The eastern section of the American Congress of Physical Therapy met in Philadelphia May 6 with the following speakers, among others:

Dr. Madge C. L. McGuinness, New York, Physical Therapy in Gynecology.
Dr. Richard Kovacs, New York, Recent Problems in the Interpretation of the Physiologic Changes in Arthritis and Their Treatment by Physical Therapeutic Measures.
Della W. Bronk, Ph.D., Philadelphia, Biophysics and the Future of Physical Therapy.
Dr. Frank H. Krusen, Philadelphia, Therapeutic Light Sources and Their Physiologic Action.

The midwestern section of the congress held its spring session in Peoria, Ill., May 15. Among speakers were:

Dr. Frank H. Ewerhardt, St. Louis, Treatment of Flaccid Paralysis.
Dr. Disraeli W. Kolak, Chicago, Effect of Ultraviolet in Sacro-Iliac Arthritis Associated with Sciatic Pain.
Dr. Frederick L. Wahrer, Marshalltown, Iowa, Electrosurgery in Relation to the Tonsil Problem.
Dr. John Stanley Coulter, Chicago, Evaluation of Physical Measures in Arthritis.

The western section met in Del Monte, Calif., April 23, and presented a program including the following speakers:

Dr. William J. Kerr, San Francisco, Treatment of Raynaud's Disease.
Dr. William W. Worster, San Gabriel, Calif., Use and Abuse of Colonic Therapy.
Dr. Norman A. Epstein, San Francisco, Treatment of Syphilis with Hyperpyrexia Produced by Diathermy.
Dr. John Severy Hibben, Pasadena, Physical Agents in the Treatment of Pneumonia.

Foreign Letters

LONDON

(From Our Regular Correspondent)

April 29, 1933

The British Medical Association and the London County Council

The trouble between the British Medical Association and the London County Council over the appointment of consultants and specialists to the council's hospitals, reported in previous letters is not the only one. The reorganizing activities of the council, which is the largest employer of physicians in the world and has only recently acquired so much power by taking over the duties of all the public health authorities of the metropolis, were bound to bring it up against the association. The council now proposes to adopt a uniform scale of charges for the treatment of outpatients, including casualties, accidents and other emergencies. But the objection is made that this encroaches on the work of the voluntary hospitals and is a direct challenge to the private physician. The new scale of charges includes the following: (1) medical and surgical, consultations and treatment, including massage and electrical treatment, 36 cents for an attendance, (2) dental attendances, provided treatment is actually given and excluding attendance for the provision and fitting of dentures 36 cents for an attendance, (3) roentgen examinations from \$2 to \$7, with 50 cents for each additional film taken at the same sitting or for a film taken away. No charges are to be made for examination after former inpatient treatment, for antenatal and postnatal attendances, or for first attendances, except for roentgen examination. The attitude of the British Medical Association is that any incursion by the London County Council into ordinary outpatient activity comparable with the outpatient work of the voluntary hospitals would gravely endanger the position of the private physician, unless the patients were seen only on the recommendation of their own individual physician. The British Medical Association has recently introduced a model form for use by the physician in sending his patients to a hospital, either voluntary or municipal.

The Defects of the Modern Dietary

Dr Chalmers Watson, senior physician of the Edinburgh Royal Infirmary, delivered a lecture to the Glasgow and West of Scotland College of Domestic Science on defects of the national diet. He said that while in the past forty years the health of the nation had materially improved in some directions through improved hygiene in other directions, such as the increasing incidence of dental disease increasing maternal morbidity, the prevalence of tonsils and adenoids, appendicitis and allied abdominal conditions and the increased incidence of cancer, the reverse was true. There was an increasing tendency to associate these results with the changes that had taken place in the feeding habits of the people during that period. These changes were a departure from the use of fresh natural foods, reliance being placed on substitutes regarded as just as good. But though in themselves wholesome, these substitutes lacked to a greater or lesser degree the vital properties included under the general term vitamins which were present in fresh food. In response to the popular demand for white bread, the miller removed the most nutritious element in the wheat grain. The bulk of the milk supply had its nutritive value materially lessened by pasteurization. The natural sugar present in vegetables and fruit was replaced by an extracted and overrefined product lacking the properties of natural sugar. In general overuse was made of artificially preserved foods. He considered that the public would be ill advised if it looked to the addition to the diet of artificially prepared vitamin

preparations as a solution for the deficiency. Diet should be, so far as possible, selected from good fresh untreated milk, butter, oatmeal a daily supply of fresh fruit, vegetables, eggs, fish and home-grown meat food.

Reorganization of Irish Hospitals on the Basis of the Sweepstake Fund

The immense sums derived by the hospitals of the Irish Free State from the gambling spirit of the world, mentioned in previous letters, have given rise to special legislation in the dail. A bill has been introduced by Dr Ward, parliamentary secretary to the ministry for local government and public health. In 1931 a commission was appointed by the minister of justice to report on the division of the sweepstake monies between the hospitals. Many of them showed a lack of appreciation of the proper lines of development for the country's needs. The single anxiety of the majority was to obtain the largest possible award from the sweepstake funds. Building programs were in most cases hastily considered. Too many institutions specialized along the same lines, to the neglect of curative medicine. The minister would control the reorganization of the scheme as a whole. The bill would establish a hospitals commission with power to survey the existing hospital facilities and consider every application for a grant. In future medical research, institutions would be included in the sweepstake list.

PARIS

April 12, 1933

The Rights and Duties of the Surgeon

The Society of Legal Medicine discussed recently the subject "If a surgeon, during the course of an operation, discovers a lesion that he had not diagnosed previous to the operation, and that the patient did not know existed has he the right, as the representative of the patient's interests, to perform a more complete intervention than he had planned?" In some instances patients, following an operation more mutilating than that to which they had agreed, have sued the surgeon for damages, and, in spite of the fact that health was restored, have won the suit. In principle, a surgeon has the right to perform only the operation concerning which a formal agreement was entered into with his patient, for the consent of a patient to an operation is absolutely necessary, by virtue of the principle that every person is the sole arbiter in matters affecting his own body. When, however, the patient is under anesthesia, it is impossible to interrupt the operation and to revive the patient in order to ask him his opinion. The courts have admitted that the surgeon may be content to accept the opinion of the husband in a matter involving a more extensive operation on the wife. Recently, the court of Lannion refused to allow a woman her claim for damages in the case of a surgeon who had operated on her for a tumor of the breast, although he had stated that the tumor was benign and would require only a simple excision. During the operation however, he discovered that the tumor was a cancer. After securing the consent of the husband, he removed the entire breast and likewise excised glands in the axilla. The patient recovered but demanded 200 000 francs (\$8 000) by way of damages. The court denied the claim. The courts are less inclined to admit that the consent of the wife is valid when the husband is under an anesthetic, for she is not so good a judge of a possible diminution of capacity that might result from a more mutilating operation on her husband. Then, again the husband may be absent, and the patient, brought in an emergency to the hospital may be alone. The medicolegalists at the meeting expressed the view that the condition of absolute necessity absolved the surgeon from all blame, even if the operation proved fatal or caused an unforeseen mutilation, but that, if

the matter was brought before the courts, the surgeon would be required to prove that such necessity existed. In case of a claim for damages being made by the patient or her family, the court should not grant an indemnity unless it was proved that the surgeon committed an unquestionable professional misdemeanor recognized by expert witnesses. A typical case is that of a patient who consented to an operation for intestinal strangulation but who on awakening, discovered that an artificial anus had been constructed for which he had not been prepared. In such a case if any want of dexterity on the part of the surgeon can be proved, he may be subjected to a penalty. The same is true in case of an important abdominal eversion after a laparotomy. The society discussed the case in which a surgeon is induced to operate on a patient against the patient's desire, the latter declaring that he prefers death to an operation that might save him. It is the surgeon's duty to prevent suicide. It has, however, occurred that women refuse, through fear, a laparotomy for a ruptured ectopic pregnancy or even the simple application of forceps. In case the patient recovers, the surgeon runs no risk, but in case of accident or of death, he will have great difficulty in proving his good intentions. Some one present cited the humorous case of a man who was found hanging to a limb of a tree, life being almost extinct. A good Samaritan passing by hastened to cut the rope with his knife. The man in falling suffered a fracture of the thigh and remained lame for life. He summoned his benefactor before the courts which condemned the latter because in their opinion he should have used greater precaution in rescuing the hanged man.

Proposed Reorganization of Sanitary Services

The Parti social de la sante publique, an association of physicians, hygienists and sociologists has protested against the distribution, among a dozen different ministries of the services connected with medicine and hygiene. There is a technical service of this kind in every ministry which gives rise to confusion, the undue expenditure of funds and duplication of effort. The remedy appears to be a concentration within a single organization, the ministry of public health. The Academy of Medicine is under the control of the ministry of public instruction, the same as the faculties of medicine. Epizootics and the surveillance of food products are in the hands of the ministry of agriculture. The health services of the railways and other common carriers are under the supervision of the ministry of public works. The departments of war, navy and the colonies have their own medical services. A vast saving in personnel and equipment would result from an amalgamation of all these services under one management. Thus far all that has been accomplished is the creation, within the ministry of public health, of two large commissions in which all these services have a representative, who has little authority. A long time probably will elapse before such centralization is brought about since each of these organizations finds it advantageous to function in an isolated manner under conditions in which medicine is treated as a secondary factor.

The International Congress on Child Welfare

The Congres international pour la protection de l'enfance will be held in Paris July 4-9, under the chairmanship of Mr. Strauss, senator and member of the Academy of Medicine. The work of the congress will be divided into eight sections, as follows: (1) motherhood, prenatal consultations, (2) early childhood, the importance of mothers possessing a technical education in the campaign against infant mortality, (3) later childhood (children aged 3-14), supervision of the physical development of the child during the school period, (4) adolescence (ages 14-18), supervision of the physical development of the adolescent, (5) abnormal children, practical means of teaching a trade to abnormal children and of facilitating its pursuit, (6) social service, social aid for the child of school age, (7) wards of the state, organization of legal guardian-

ship of illegitimate children, (8) various communications questions dealing with the protection of mother and child and not coming under the head of questions proposed by the other sections. Additional information in regard to the congress may be secured by addressing Secretariat général, 26 Bld. de Vaugirard, Paris (XV^e).

BERLIN

(From Our Regular Correspondent)

May 8, 1933

The Reorganization of the Medical Profession

Dr. Haedenkamp, the Berlin plenipotentiary of the medical syndicates, has been summoned to serve as a commissary in the federal ministry of labor, to elaborate the new organization of the federal system of health insurance. Following a report on the reception of the leaders of the medical organizations by chancellor Hitler, he expressed his views on the physician in the new state. Professional politics in medical circles, in the sense of the exercise of power or the employment of force measures, will no longer exist. The influence and authority of the medical profession in the new state will be based on accomplishments and on nothing else. "It is not the array of expensive equipment nor the superabundance of medicines and remedies that effect the cure but rather the living human forces that are emitted by the personality of the physician."

Haedenkamp states further that the work of welding the medical profession of Germany into the new state is proceeding regularly in accordance with a clearly conceived plan whereby the medical profession shall be guided by a central government authority, although it will administer its own personal affairs in a general way. It is not simple to weld together the medical organizations, the leagues representing economic affairs and the professional and legal organs of the body of physicians. The medical care of persons insured in the health insurance societies must not be endangered or disturbed. The reorganization of the economic central body will be brought under the control of the state and will have to be guided by government authority. The existing *aerztekammern* or chambers of physicians, will be dissolved and the local groups will then constitute the basal structure for a *reichsärztekammer*, or federal chamber of physicians. The new organization of medicine will consist of two parts, one subdivision having to do with purely professional matters and political matters affecting medicine, and the second subdivision with economic affairs and social politics. With respect to the division of tasks and duties, the preeminent duties of the profession lie in the fields of the care of public health and race hygiene or eugenics.

By using existing bodies and regulations, a legally recognized council on medical ethics and a system of health, disability and old age insurance for physicians must be set up. The existing *Deutsche Aerzteversicherung* may be used as a nucleus.

The whole structure can rest on the legal basis of a federal *reichsärzteordnung*, or a federal council on medical ethics. The physician can thus finally emerge from the *reichsgewerbeordnung*, or the federal industrial council in which he is classed with industrial workers and can attain to a legal status in keeping with the importance and the heavy responsibilities associated with the tasks that he must fulfil as the defender and promoter of public health.

Heart Surgery

Professor Stich, surgeon of Göttingen, spoke recently before the Hanover Medical Society on 'Observations on Heart Surgery.' One need go back no further than to Billroth to find a surgeon who regarded operations on the heart impossible. Only a year elapsed after Billroth's statement before Block of Danzig did his first work on the heart, although fifteen years passed before Louis Rehn performed the first successful heart

suture. Without operation 85 per cent of persons suffering heart injuries die, whereas 79 per cent of the persons successfully operated on are restored to full working capacity. Withdrawal of the heart from the pericardium often causes fibrillation. Injury of the coronary artery is nearly always fatal. Tension of the pericardium demands prompt intervention. From 30 to 50 per cent of patients with heart injuries die as a result of secondary manifestations of pericarditis. Bacteria that have been brought in by the trauma must be removed. Recent penetrating projectiles are usually removed, older foreign bodies are allowed to remain if they produce no symptoms. The pathologist often finds foreign bodies in the heart, though the patient did not know of their existence. Calculi of the pericardium arising from fibrinous excretions or pericardium bodies produced by the echinococcus (about fifty cases of which are described in the literature) are not amenable to surgical treatment. In effusion into the pericardium pain is caused more by the suddenness of the event than by the quantity of the fluid, which may be 750 cc without grave danger. Puncture of the pericardial effusion and pericardiectomy in purulent effusion are no longer rare interventions. In all forms of pericarditis indurations may develop. In accretio pericardii the heart appears enlarged on percussion and also in the roentgenogram, in concretion pericardii and complete adhesion of the heart to the pericardium, the heart is small and shows in the roentgenogram evident lime deposits extending into the pericardium. The prognosis in case of purely internal treatment is not favorable. The mechanical process requires elimination through operation. Thoracotomy in accretio pericardii gives good results (17 per cent mortality) if the diagnosis is accurate and the technic is good. Surgical intervention in concretion pericardii involves, however, a much more difficult technic and a much higher mortality (about 25 per cent). Although the results of surgical treatment in angina pectoris and heart failure (division of the depressor and the sympathetic nerves) are not encouraging, there is no reason for resignation.

Health Exposition in Berlin

In the Berlin "Sport Palace" the first Exposition of Health Sport and Hygiene, of Greater Berlin, was opened, April 27, with an address by Ministerialrat Dr. Conti, who since the political overthrow of the Prussian administrative bureau of medicine has held a leading position. He emphasized that it is not the task of a nation to create solely model institutions for the sick and the blind. Much greater importance attaches to improving the health of the people as a whole. The purpose of this health survey is to promote that idea. The revolutionary changes in the public health system have not yet been completed. The medical profession had already shown a tendency to try to get away from overspecialization. The power of the state will exercise the necessary control in order to unite all divergent movements dealing with therapeutics, housing, nutrition and physical education on the basis of their contributions toward the improvement of the health of the people as a whole.

Numerous societies, establishments and institutes in the field of hygiene have taken part in the health survey.

Activities of the German Hygienic Museum

In addition to the continuous work of the Deutsches Hygienemuseum in Dresden, which supplies the whole German Reich with material on subjects pertaining to health, mention may be made, in connection with the activities of the year 1932, of the carrying out of the annual health survey, which comprised three exhibits and numerous lectures and film presentations. During the year, three traveling exhibits were constantly on the move, namely, 'Man in Health and Disease,' 'Healthy Women Mean a Healthy People' and 'The Fight Against Cancer.' In Germany these three exhibits were shown in 1932 in twenty-one places and attracted 400,000 visitors. In addition, exhibits were sent to some foreign countries, chiefly

Austria, Sweden and the Netherlands. The traveling exhibits as a whole were set up in twenty-eight places at home and abroad and more than 700,000 persons visited them. More than 20,000 photographs were lent to illustrate lecture courses.

Roentgenologic Demonstrations of the Human Brain in a Living Subject

Dr. Radović and Dr. O. Meller of Bucharest report in the *Klinische Wochenschrift* on a new method for the roentgenologic demonstration of the human brain in the living subject. They experimented with methods of demonstrating in roentgenograms the plastic relief of the central nervous system by obscuration of the spinal fluid with the aid of a contrast medium. For this purpose they injected a colloidal solution of thorium dioxide into the spinal canal or into the brain, first into the dead bodies of new-born infants and later also in rabbits, dogs and apes. The sulci between the convolutions of the brain appear as black narrow stripes, whereas the convolutions stand out in relief. The spinal cord itself appears to be limited by two black parallel bands, which correspond to the shadow-producing spinal fluid. Since, after from one to three months, the relief outlines of the central nervous system have become much paler and the dark stripes appear only as very fine lines, it may be assumed that the injected substance is gradually absorbed and disappears from the surface of the brain. The animals treated in this manner do not behave differently from the controls. The authors believe, therefore, that the favorable results justify the use of this or similar technic on man. The use of thorium salts for a demonstration of other organs has been known for several years.

PRAGUE

April 21, 1933

A Physicians' Savings Bank

The annual report of the Savings Bank of Czechoslovakian Physicians has just been published. The savings bank was founded in 1906 and it has had a steady and continuous growth. The bank tries to concentrate in its hands the financial resources of Czechoslovakian physicians, veterinarians and pharmacists. It will soon have 3,000 members. The administrative center is in Prague, but there are branches in two provincial capitals, Brno and Bratislava, and one in Kosice. The bank collects the savings of physicians, veterinarians and pharmacists and places them out as loans to members of the same professions who need them for investments in new offices, homes or sanatoriums. Only through the help of this institution could the central Home for Czechoslovakian Physicians have been erected in Prague. Another important function of the bank lies in the fact that it takes over the liabilities of those who do not pay regularly to the physicians and through its machinery enforces the payment of fees. This has become an important function not so much with private patients as for insurance bodies which find themselves in a difficult financial situation and do not pay their physicians in time. The physicians receive their respective amounts as loans from the bank, which are ultimately covered by the recovered payments including the interest which is paid to the bank for the loan. The board of directors of the bank has always adhered strictly to a conservative financial policy, which has meant for physicians the conservation of their property in spite of the turbulent times. The bank distributed a dividend of 7 per cent for 1932. In addition, it is able to use its surplus for gifts which usually aim at some activity for the advancement of the medical profession. Two years ago a donation was made for the erection of a consultation station for young physicians and medical students, last year a gift was made toward the organization of a study on the present status of medical practice in Czecho-

slovakia. The main functions of the bank are in the hands of the heads of the Czechoslovakian medical organization and consequently the physicians are guaranteed that the bank's interest lies exclusively in the promotion of the well being of its members. The depression which has just passed has given to physicians in Czechoslovakia an opportunity to appreciate the advantages of such an institution.

A Professional Automobile Club

The physicians of Czechoslovakia have an active automobile club, which bears the name of Aesculapius. The organization now comprises about 800 members. The members have the right to use a sign on the car which gives them certain privileges but imposes also certain obligations. The sign is a red cross in a blue field with a golden snake in the middle. It is placed in the front and back of the car and can be illuminated. The sign can remain uncovered only as long as the physician is in service. Every such car must have a standard equipment for first aid to be given by its occupants in case of emergency. The traffic regulations in most large cities give the cars with the sign preference in the traffic and allow parking in places where it is prohibited to other cars. A certain lightening of the tax burden on members of the club has also been attained. Similar medical clubs have been formed in other states of central Europe and at the present time an international union of medical automobile clubs is being considered. The reason for it is that it is intended to obtain for physicians who belong to the club some relief from passport restrictions while crossing the state frontiers on medical duty. The club has been also active in the development of safety first propaganda not only among its members but also among the members of other automobile clubs. It has also deliberated on technical questions concerning first aid in the case of automobile accident, of the equipment of first aid stations and of the organization of first aid service.

The Controversy with Sickness Insurance Bodies

The relation of general hospitals to insurance bodies is being discussed in medical circles. According to the present law on sickness insurance the insured is entitled to treatment for four weeks in the hospital at the expense of the insurance bodies, a provision which has been used extensively by the insurance corporations because they find that hospital treatment has many advantages for their patients. The period of disablement is usually shortened by treatment in a hospital. According to the present practice the public hospital authorities do not allow any direct interference of insurance authorities in the treatment of the insured while they are in the hospital. This is a point of dispute between general hospitals and insurance bodies, the latter maintaining that it would be advantageous for them if they could control the progress of the treatment in the hospital, as they could eliminate waste. They maintain that instances could be found wherein the patient was kept in the hospital longer than his actual situation required. They suspect that hospitals do so from financial considerations. The hospitals on the other hand, complain that they usually receive the patient without any record of previous sickness and consequently the examination of the patient has to be done from the start. When the patient is discharged from the hospital there is usually no follow-up service which would guarantee to the hospital that the results obtained will be permanent. The result of this situation was a tendency on the part of some insurance bodies to erect hospitals of their own. Such an institution has been erected in Prague, where the respective sickness insurance body claims excellent results. The medical profession does not look favorably on this movement. It fears that the standard of service in the hospitals might be endangered through the interference of lay people putting into the leading positions of the hospitals physicians not so much according to their professional qualification as according to their political influence.

Some form of readjustment in the present hospital service must be made aiming at a closer connection of hospitals with the insurance bodies if the construction of special hospitals for the insurance corporations is to be prevented. This is generally admitted and ways are being considered by which this can be carried out most advantageously.

The League Against Rheumatism

The report of the Czechoslovakian League Against Rheumatism was presented at a recent annual meeting of this organization. The league was organized in Czechoslovakia in 1927 as a national committee of the international league for the campaign against rheumatism which has its seat in Amsterdam. The main activities of the league were concentrated on the advancement of knowledge on the occurrence and treatment of rheumatism in Czechoslovakia. An attempt was made to collect data on rheumatism among the insurance patients. To insure a correct diagnosis, a census of only those who have been sent to watering places for the treatment of rheumatism was carried out among the insurance bodies of the whole state. The league published last year a treatise on rheumatism. Besides many lectures before medical societies by the officers of the league, a graduate course for physicians on the treatment of rheumatism was organized in Prague. The erection of a special consultation station for persons having rheumatism is being prepared in one of the large industrial centers of Czechoslovakia. The league is pleased that its campaign against rheumatism brings many rheumatic patients to Czechoslovakia for treatment.

Cleanliness Week

The Czechoslovakian Red Cross organizes every year at Easter an educational week for the advancement of the health of the people. A feature of these campaigns is the support which the Red Cross has been able to obtain from the public authorities. The week is terminated every year by a public session in the parliament which is presided over by the president of the chamber of deputies and is attended by many high officials of the state, including the president of the republic. This year the slogan for more cleanliness was used with the idea that the unemployed could help improve the cleanliness of homes, streets, markets and public lots. This slogan seems to have been a particularly happy choice because great interest was aroused by the campaign. The ceremonies this year impressed authorities so much that a proposition for a similar movement on an international basis is being considered for the world conference of the League of Red Cross Societies in Tokyo next year.

A New Orthopedic Department

A new orthopedic department has been opened in Brno at the medical school. Orthopedic departments have been opened in recent years in Prague and Bratislava. The services of a young surgeon Prof. B. Frejka have been secured for the direction of this new institution. The department has 125 beds. The department is not to confine its activities merely to hospital work. Stress is to be laid on preventive work. The clinic will endeavor to become the center of scientific research. Its main function will be the education of young physicians. The clinic will also cooperate with other institutions for the care of crippled children and function as a center for the treatment of complicated cases.

British Surgeons Visit Prague

The Moynihan Chirurgical Club of Great Britain was lately the guest of the first surgical clinic of the Czech faculty of medicine of Prague, twenty-eight members of the club with their families visited the surgical institutions of Prague. The program comprised lectures and demonstrations, which were organized by Prof. A. Jirasek, chief of the first surgical clinic of Prague. The visitors attended operations in the clinics and visited also the State Institute of Public Hygiene of Prague.

the new general hospital of the city of Prague and other institutions. This visit was appreciated by the medical profession of Czechoslovakia. This was expressed in several speeches.

Social Insurance in Austria

Concerning the organization of social insurance in Austria further details have been announced from which the following figures have been taken. The many *krankenkassen* scattered throughout the country may be divided into six groups: (1) industrial workers, with about 1,000,000 members and compulsory insurance, (2) agricultural workers, 300,000, (3) mercantile and private employees 280,000, (4) government employees, 170,000, (5) employees of transportation companies, including railways, 170,000, and (6) employees of the municipality of Vienna, 45,000 making a total of about 1,965,000 members. Of this number 100 per cent are insured against disease but only 60 per cent are insured against loss of employment, that is to say, about 40 per cent are enrolled under family insurance. The average monthly income of members of the *krankenkassen* is 156 shillings or about \$22, the highest monthly income is only 200 shillings or about \$30. On this basis, the insured receives a weekly sick benefit during illness or a lump sum compensation in case of accident. The members pay two thirds and the employer one third of the monthly insurance premiums, which average about 24 shillings or \$3.60. The insured member thus pays from 10 to 13 per cent of his income to the *krankenkasse*, the maximum figure being 28.50 shillings, or \$4.28, for workers. In the case of employees who carry also old age pension, the monthly premium amounts to about 14 or 15 per cent of the wages received. The total receipts of the *krankenkassen* in 1931 were 207,000,000 shillings, or \$31,050,000, 93 per cent of which sum was expended for insurance benefits: 60,000,000 shillings for medical aid, 30,000,000 for medicines, 41,000,000 for hospital care and 62,000,000 for sick benefits. For accident insurance, 36,000,000 shillings was received and expended.

Refusal of Roentgenologists to Participate in Congress to Be Held in Germany

The political upheaval in Germany, with its racial intolerance, has received an unusual disavowal on the part of an eminent scientific body in Austria. For the Congress of the German Roentgenologic Society which is about to convene in Bremen Professor Kienböck, a recognized authority in this field, was chosen last year to serve as chairman. He is also president of the Austrian Roentgenologic Society in Vienna. Since his mother was Jewish, word came from Germany that it no longer seemed desirable that he should serve as chairman. Thereupon, Professor Kienböck, deeply indignant, naturally resigned his position. But the Austrian Roentgenologic Society took the side of its president and decided after this affront, to refuse to participate in the sessions of a society that regards anti-Semitic considerations as of more importance than scientific problems. The congress in Bremen will therefore be held without representation from the Vienna school, which occupies a preeminent position in the field of roentgenology.

The Role of the Tonsils

In an address before the *Gesellschaft der Aerzte* in Vienna, Dr. S. Peller discussed the results of his study of 17,000 children with respect to the influence of the tonsils on growth and weight. The children were those inspected by the Vienna Institute for Vocational Guidance, following their completion of the elementary school and their ages ranged from 13½ to 16. He found that 13 per cent of the children had had the

tonsils removed (11 per cent of the boys and 16 per cent of the girls), 11 per cent of the total still had hypertrophic tonsils. Peller found that the male children with hypertrophic tonsils were several centimeters (from 2 to 4) shorter and from 2 to 4 Kg lighter than children of corresponding age who were subjected to tonsillectomy several years previously. In the girls, the conditions were somewhat different. The tonsillectomized girls aged from 14 to 14½ years, were from 2 to 2.5 Kg heavier than the girls who have retained their tonsils. The height of girls whose tonsils were removed years previously was not materially different from that of girls who had hypertrophied tonsils. The girls with hypertrophied tonsils began later to menstruate than those whose tonsils were removed early. At the age of 14, 36 per cent of the former and only 18 per cent of the latter were not yet sexually mature, as compared with a general average of 23 per cent for girls of corresponding age and at the age of 14½ the figures were 27, 14 and 15 per cent, respectively. Dr. Peller concludes from these observations that the tonsils have a regulatory mechanism affecting growth, as a retarding factor—at least during the ages 13-16 years, particularly in boys, whereas in the girls they appear to affect only the weight. Removal of the tonsils produces in boys greater height, but in girls only greater weight, the height not being influenced. The tonsils affect the onset of sexual maturity in girls, not that their removal causes an acceleration of sexual maturity but merely tends to make the onset correspond more closely to normal. Scarlet fever and diphtheria are noted much more frequently in the history of juveniles who have hypertrophied tonsils or who have undergone tonsillectomy than in the general average of the same age. Dr. Peller concludes that the increased predisposition to scarlet fever and diphtheria in children with hypertrophied tonsils is not due to such hypertrophy but that the two conditions are parallel manifestations. In children who had had scarlet fever or diphtheria or both diseases, pathologic tonsils were much more frequent than in children who had not had either scarlet fever or diphtheria.

Infectious Diseases in Austria

The report of the Central-Gesundheits-Amt for Austria reveals that during the months of January and February, 1933, infectious diseases in Vienna show a slow but steady decline with respect to the most important types. Scarlet fever receded about 15 per cent, diphtheria 16 per cent, typhoid 5 per cent, paratyphoid 12 per cent, chickenpox 25 per cent and poliomyelitis 30 per cent as compared with the end of last year. Not a case of genuine smallpox or cholera was observed. In the whole territory of Austria, with 6,750,000 inhabitants, only 971 cases of typhoid, 804 of paratyphoid and 80 of dysentery were observed last year. Through the vigilance of the public health service the carriers of bacilli have been controlled and their employment in many instances has been prohibited (particularly in shops where food products are sold) and in other cases has been greatly restricted.

Marriages

CHARLES T. YARINGTON, Moravia, N. Y. to Miss Florence Jane Hutchinson of Ardmore, May 6.

ROYALE H. FOWLER, Newark, N. J., to Mrs. Pauline M. Perrine of Princeton, April 21.

WILLIAM COPELAND COOK, Cincinnati, to Miss Lucille Van Meter of Delaware, March 24.

BENJAMIN HORTON KENDALL, Shelby, N. C., to Miss Ruby Spratt of Marion, May 1.

JACOB NATHANIEL BAILEY to Miss Nell Cunliff, both of Paducah, Ky., May 8.

L. WILLIAM MORSMAN to Miss Mabel Hay, both of Hibbing, Minn., recently.

Deaths

John Chalmers Da Costa ♂ for about forty-five years a member of the faculty of Jefferson Medical College died at his home in Philadelphia, May 16, following a long illness due to arthritis deformans. Dr. Da Costa was born in Philadelphia in 1863. He graduated from the University of Pennsylvania in 1882 and from Jefferson Medical College in 1885 in which year he became a resident physician at the Philadelphia Hospital and in the following year an assistant physician. He was appointed an assistant demonstrator in anatomy at his alma mater and an assistant surgeon at the Jefferson Hospital in 1887, a demonstrator of surgery in 1891, clinical professor of surgery in 1898, and professor of surgery in 1900. In the following year Dr. Da Costa was made Samuel D. Gross professor of surgery, which chair he occupied until the time of his death. He has been surgeon to the Philadelphia Hospital since 1895 and to St. Joseph's Hospital since 1896. Among his best known writings is his *Manual of Modern Surgery*, published in 1895, which has gone through many editions. He was editor of the American edition of *Gray's Anatomy* in 1905 and of the English edition of *Zuckerland's Operative Surgery* in 1889, and a frequent contributor to the periodic literature. Dr. Da Costa was a member of the College of Physicians of Philadelphia, the American Surgical Association, the Society of Clinical Surgery, and an associate member of the Society of Gynecology and Surgery of Bucharest and fellow of the American College of Surgeons. He served gratuitously for about thirty-five years as surgeon for the city firemen of Philadelphia and of the Firemen's Pension Fund. His international reputation as a surgeon brought him many honors. Under the auspices of the Philadelphia County Medical Society, Da Costa Day was inaugurated in 1930 and the John Chalmers Da Costa Foundation established for the purpose of furthering graduate teaching under the auspices of the county society. Dr. Da Costa was a commander in the U. S. Naval Reserve forces, and during the World War accompanied President Wilson to France.

Clarence Erford Coon ♂ Syracuse, N. Y., Syracuse University College of Medicine 1898, professor of orthopedic surgery at his alma mater, past president of the Onondaga County Medical Society and the Syracuse Academy of Medicine, fellow of the American College of Surgeons, served during the World War, on the staffs of the Hospital of the Good Shepherd, Syracuse University, Syracuse Memorial Hospital, Syracuse Free Dispensary, and the New York State Reconstruction Home, West Haverstraw, aged 65, died, April 22, of *limitis plastica*, anemia and coronary thrombosis.

Ray Connor ♂ Detroit, Johns Hopkins University School of Medicine, Baltimore, 1901, formerly assistant clinical professor of ophthalmology, Detroit College of Medicine and Surgery, member of the American Academy of Ophthalmology and Oto-Laryngology and the American Laryngological, Rhinological and Otolological Society, fellow of the American College of Surgeons, served during the World War, surgeon to the Children's Free and Providence hospitals, aged 56, was found dead, April 21, of heart disease.

Owen Copp, Philadelphia, Harvard University Medical School, Boston, 1884, member of the American Psychiatric Association and the New England Society of Psychiatry, executive secretary of the Massachusetts Board of Insanity, Boston, 1899-1911, superintendent of the Massachusetts Hospital for Epileptics, Monson, Mass., 1895-1899, physician in chief and administrator, Pennsylvania Hospital for Insane, Philadelphia, 1911-1922, aged 75, died, April 18, in Seville, Spain, of heart disease.

Jefferson H. Wilson ♂ Beaver, Pa., Bellevue Hospital Medical College, New York, 1876, past president of the Beaver County Medical Society, fellow of the American College of Surgeons, on the staffs of the Rochester (N. Y.) General Hospital, Beaver Valley General Hospital, New Brighton and the Providence Hospital, Beaver Falls, aged 82, died, April 5, of cerebral hemorrhage.

Isaac Jay Furman, New York, Syracuse University College of Medicine, 1906, member of the American Psychiatric Association, formerly associate clinical professor of psychiatry, Columbia University College of Physicians and Surgeons, medical superintendent of the Manhattan State Hospital, Wards Island, aged 54, died, May 5, of cerebral hemorrhage.

James M. Wright ♂ Denison, Kan., Kansas Medical College, Medical Department of Washburn College, Topeka, 1902, fellow of the American College of Surgeons, president of the

Jackson County Medical Society, for twenty-five years a medical missionary in China, aged 62, died, February 18, of bronchopneumonia.

Lozey Lynn Harding ♂ Frankfort, Ind., Indiana University School of Medicine, Indianapolis, 1917, past president and secretary of the Clinton County Medical Society, on the staff of the Clinton County Hospital, aged 45, died, April 28, in the Methodist Hospital, Indianapolis, of uremia and interstitial nephritis.

Joseph Max Irwin ♂ St. Augustine, Fla., Washington University School of Medicine, St. Louis, 1902, past president and secretary of St. Johns County Medical Society, served during the World War, on the staff of the Flagler Hospital, aged 61, died suddenly, April 19, of heart disease.

Virgil Charles Kinney, Wellsville, N. Y., Columbia University College of Physicians and Surgeons, New York, 1902, medical superintendent of the Wellsville Sanatorium, aged 59, died, April 26, in St. Petersburg, Fla., of metastatic carcinoma of the spine and liver and bronchopneumonia.

Gideon Johannes Ferreira ♂ Duluth, Minn., State University of Iowa College of Medicine, Iowa City, 1920, county health officer, formerly health officer of Aurora, aged 38, died, April 13, in St. Luke's Hospital, of pulmonary embolism following an operation on the gallbladder.

James Daniel Currie, Hico, Texas, George Washington University School of Medicine, Washington, D. C., 1906, member of the State Medical Association of Texas, served during the World War, aged 61, died, March 9, in a hospital at Stephenville, of pneumonia.

Alphonso Isom ♂ Dumas, Ark., St. Louis College of Physicians and Surgeons, 1906, past president of the Desha County Medical Society, served during the World War, physician in charge of the Dumas Hospital, aged 47, died, April 24, of heart disease.

James P. T. Stephens, Vaiden, Miss., Tulane University of Louisiana Medical Department, New Orleans, 1900, member of the Mississippi State Medical Association, county health officer, aged 56, was killed, April 29, in an automobile accident.

George W. Mitchell ♂ Hornell, N. Y., Syracuse University College of Medicine, 1909, member of the city board of health on the staffs of St. James Mercy Hospital and the Bethesda Hospital, aged 49, died, April 26, of heart disease.

Albert Jacques St. Germain, Chicago, Rush Medical College, Chicago, 1921, aged 38, on the staff of St. Luke's Hospital, where he died, April 28, as the result of injuries received in an elevator accident in the building in which he resided.

Horace G. Harvey ♂ Denver, Missouri Medical College, St. Louis, 1887, formerly professor of surgery, University of Colorado School of Medicine, aged 70, died, April 15, of cerebral hemorrhage and chronic nephritis.

Esther Anne Ryerson, Dayton, Ohio, College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1903, aged 79, died, April 19, at the Orchard Springs Sanatorium, of uremia.

Christian Jacob Rohwer ♂ Seattle, University of Pennsylvania School of Medicine, Philadelphia, 1921, aged 42, died, April 16, in the Virginia Mason Hospital, of carcinoma of the sigmoid and pulmonary embolism.

John A. Jones, Tonkawa, Okla. (licensed Oklahoma, under the Act of 1908), member of the Oklahoma State Medical Association, aged 59, died, April 19, in the Wesley Hospital, Wichita, Kan., of carcinoma.

Joseph Sarvis Dusenbury, Conway, S. C., Medical College of the State of South Carolina, Charleston, 1890, member of the South Carolina Medical Association, aged 66, died, May 1, of pneumonia.

Henry Adoniram Vann, Boston, Ga., University of the City of New York Medical Department, 1871, member of the Medical Association of Georgia, aged 83, died, April 17, of cerebral hemorrhage.

Verdo Benjamin Gregory, Tulare, Calif., College of Physicians and Surgeons, Medical Department, Kansas City University, Kansas City, Kan., 1897, aged 63, died, April 15, of angina pectoris.

Ernest Clifford Fish ♂ Melrose, Mass., McGill University Faculty of Medicine, Montreal, Que., Canada, 1896, aged 65, died, April 25, of arteriosclerosis, chronic myocarditis and cardiac asthma.

Harley Edgar MacDonald, Redding, Calif., Ohio Medical University, Columbus, 1906, member of the California Medical Association, aged 54, died suddenly, April 20, of coronary embolism.

William Lawrence Burns * Cumberland Md , University of Maryland School of Medicine, Baltimore 1908, on the staff of the Memorial Hospital, aged 50, died, April 1, of coronary occlusion

Adam Donaldson Wilson, Fresno Calif University of Edinburgh Faculty of Medicine Edinburgh, Scotland 1886, aged 69, died, March 12, of aneurysm of the abdominal aorta

Allen Salter * Lena Ill College of Physicians and Surgeons Chicago 1893, aged 68, died April 22, in Freeport, of chronic myocarditis arteriosclerosis and cerebral thrombosis

Napoleon B Beakley, England Ark University of Arkansas School of Medicine, Little Rock, 1893 president of the school board, aged 69, died April 15 of heart disease

William Joseph Lee, Panama City, Fla Kentucky School of Medicine, Louisville, 1893, member of the Florida Medical Association aged 61, died, April 22 of heart disease

Fred William Schecher, St Bonifacius Minn , Chicago College of Medicine and Surgery 1910 aged 48 died suddenly, April 7, of coronary disease and hypertension

Daniel Alexander McClenahan, Hamilton, Ont , Canada Trinity Medical College, Toronto, 1894 district health officer of Hamilton, aged 66, died suddenly, March 4

John Joseph Kosker, Nanticoke, Pa , University of Pennsylvania School of Medicine Philadelphia 1920 aged 39 died, January 25, of influenza and acute myocarditis

Joseph C De Wane * Wolf Point, Mont Milwaukee Medical College, 1909, aged 50 died, May 2, of erysipelas and adenitis of the cervical glands

Robert W Bowling, South Pasadena Calif , University of Louisville (Ky) School of Medicine 1893, aged 61 died April 18, of cerebral hemorrhage

Edward Joseph Sweeney, Springfield Mass Jefferson Medical College of Philadelphia, 1907 aged 54, died March 14, of coronary thrombosis

Edwin Nathan Johnston, Minneapolis State University of Iowa College of Medicine, Iowa City, 1895 aged 64, died, April 10, of heart disease

Joseph Dallas Smith, Columbus Ohio, University of Wooster Medical Department, Cleveland, 1880, aged 88, died, April 26, of heart disease.

Peter E Brown, Ste. Anne de Bellevue, Que. Canada McGill University Faculty of Medicine Montreal, 1863, aged 96, died, February 28

Walter S Hunter, Greenwood Del , Medico-Chirurgical College of Philadelphia, 1904 aged 51 died suddenly, April 23, of heart disease

Joseph T Arthur Gauthier, Valleyfield Que. Canada, Laval University Faculty of Medicine, Quebec, 1894, aged 66 died February 5

Henry Johnson Arnold, Barnesville Ohio Ohio Medical University, Columbus, 1898, aged 64, died, April 26, of cerebral hemorrhage

Francis Octave Eugene Larue, St Flavien, Que , Canada Laval University Faculty of Medicine, Quebec, 1884, aged 73, died in January

Bureau of Investigation

THE ADLER TREATMENT

Another Flier in the Cancer-Cure Field

For some time inquiries have been coming in regarding the so-called Adler treatment for cancer A letter just received (May 6) from Dr Benjamin S Levine of Brooklyn is somewhat typical Dr Levine writes in part

I called to see a patient of mine who has an extensive metastatic cancer of the breast with marked cachexia and they showed me a pamphlet issued by the Adler Laboratories of 591 Summit Avenue Jersey City New Jersey the title of this pamphlet being Adler Treatment of Neoplastic Diseases The name of a Dr William J Poulin is mentioned as the medical director

This laboratory furnished these people with a fancy blue bottle with a silver label in which there were some hundred red-colored capsules which contained a gelatinous substance for which they paid \$10.00 I would appreciate any information on this matter that may be on file at your office

The "Adler Treatment of Neoplastic Diseases" is said to have been 'perfected' by one Louis Adler, who seems to have been in the 'cancer cure' business for some years Louis Adler lives in Newark, N J but the so-called Adler Laboratories, Inc, operate from Jersey City, N J

Can Cancer Be Conquered?

Write for Dr Poulin's new book for the truth about this disease It will open your eyes to the facts about cancer and its treatment There is no charge for Dr Poulin's frank and authoritative book Write for it now if you would help yourself or some stricken relative or friend Address William J Poulin M D, Adler Laboratories, 591 Summit Avenue, Jersey City, N J

An advertisement that appeared in an Ohio paper in the spring of 1932

In 1921 a Newark, N J, newspaper reported that Louis Adler of that city had been arrested for practicing medicine without a license in connection with the exploitation of an alleged cure for cancer Adler was reported to have been found guilty and fined \$200 and costs From Adler's Newark address he has put out a line of 'patent medicines,' among them being "Adler's Wonder Salve," Adler's Blood Purifier' (which seems to be another "cancer cure") and "Adler's Stomach Cleanser"

Adler Laboratories Inc, is a New Jersey corporation whose certificate was filed in April, 1932 with an authorized capital of fifteen shares of Class A and forty shares of Class B stock, both being of no par value The incorporators and officers were reported to be

LOUIS ADLER President
JACOB LEVY Vice President

ABRAHAM SEPENUK Secretary
LOUIS FORT Treasurer

Louis Adler was said to hold nine shares of Class A and one share of Class B stock, while each of the other three men were said to hold two shares of Class A and eight shares of Class B Louis Fort has been described as an electrical contractor, and Jacob Levy and Abraham Sepenuk as lawyers

The medical director of the Adler Laboratories is William J Poulin, M D Dr Poulin was born in 1884 and holds a diploma from Fordham University School of Medicine 1912 He is licensed to practice in New York and New Jersey He is not a member of his local medical society or, of course of

the American Medical Association. On one of Dr Poulin's professional cards his address is given as 1001 Park Avenue, Woodcliff N. J. According to the same card Dr Poulin is "Especially Interested in Cancers, Ulcers, Hemorrhoids, Diabetes, Hay Fever, Asthma and Allied Allergic States."

Adler Laboratories Inc., sends out a twenty-two-page booklet as part of its advertising. According to this booklet, Louis Adler is a Hungarian chemist who "during the course of his researches and experiments developed a theory" that cancer is due to "the accumulation in the system of poisonous waste matter." The booklet quotes indiscriminately such scientific extremes as W. Arbuthnot Lane, J. H. Tilden, William F. Koch and William J. Mayo and Francis Carter Wood.

Nowhere in the booklet is there any information on what constitutes the Adler treatment although an entire page of the booklet is devoted to the alleged answer to a question which forms the caption of the page "What Is the Adler Treatment?"

**Excerpts of Report by Dr. Bela Teglassy
CHIEF PHYSICIAN, ASSISTANT PROFESSOR OF THE
CLINIC OF THE UNIVERSITY OF BUDAPEST**

My dear Mr. Adler:

I did not desire to give an opinion regarding your treatment until I had proceeded far enough in my experiments to be able to render an accurate report of the results.

I concentrated my efforts on cancer and ulcers as you requested.

I have reached the point where in about four to six weeks I shall insert an article in one of the newspapers concerning my experiments. I shall forward a copy of this article to you.

I plan to use the following headline in this article: "Medicinal Handling and Care of Cancer and Ulcers Through the Digestive Organs." On describing the wonderful effects of the remedy, I shall refer to it as the invention of our compatriot, Louis Adler, now living in Newark, New Jersey, with the aid of an assistant professor of the clinic.

Experience in the United States and also here up to the present, shows that it is a wonderful remedy.

If you agree with me as to the writing of that article, please inform me of your consent.

I am not sparing time, energy and work and shall not tire until we convince the world of the results that are achieved by your remedy.

I am at work with heart and soul and all my knowledge, and we cannot but succeed.

In a short time the world will know your remedy.

My only request to you now is to send me more of the capsules so that I may continue my work without interruption.

I am confident that when I publish my article in the paper I shall be besieged for the remedy.

(Signed) Dr. Bela Teglassy

Photographic facsimile (greatly reduced) of the alleged letter of Dr. Bela Teglassy to Adler.

The nearest the booklet comes to giving information on this point is a vague statement to the effect that the Adler treatment is a compound "prepared in capsule form entirely of organic products containing no drugs and no poisons." With each booklet that is sent out is a four-page diagnosis blank, typical of those used by mail-order medical concerns. It is emphasized that it is unnecessary for any patient to come to New Jersey, and the statement is made in italics:

'The Adler treatment can be administered at home by the patient himself or by some member of his household.'

The prospective patient is warned that should he consult the physician who has treated him and seek his aid in filling in the diagnosis blank, he should not "permit him [the family doctor] to discourage you in the Adler treatment." It appears that the Adler treatment, although based on the theory that cancer is due to "the accumulation in the system of poisonous waste matter," differs according to the location of the cancer.

To those who have an "external" cancer the cost for a treatment is \$15, to those with an "internal" cancer the cost is but \$10.

In the same booklet issued by the Adler Laboratories, much space is devoted to the reproduction of what is claimed to be a report by Dr. Bela Teglassy of Budapest. A letter purporting to be from Dr. Teglassy to Adler is reproduced, and a notary public of New Jersey swears that it is a true translation of the original written in the Hungarian language by the Chief Physician and Assistant Professor of the Clinic of the University of Budapest, Dr. Bela Teglassy. In this letter Dr. Teglassy states in effect, that after experimenting with Adler's cancer cure, 'he had reached the point where, in a short time he was going to insert an article in one of the [Budapest?] newspapers concerning my experiments. The letter states further that Dr. Teglassy plans to use "the following headline in this article: 'Medicinal Handling and Care of Cancer and Ulcers Through the Digestive Organs.'" Dr. Teglassy is also quoted as stating that he intended to refer to the cancer cure 'as the invention of our compatriot, Louis Adler, now living in Newark, N. J.'" The letter closed with the request on the part of Dr. Teglassy that Adler send him some more of his treatment' because, the doctor stated, he was confident that when he published his article in the paper he would be 'besieged for the remedy.'

The Bureau of Investigation looked into this matter and learned several things of interest. It found first that Dr. Bela Teglassy seems to be much more important in politics than he is in medicine. In 1931 Dr. Teglassy was elected in a provincial district to the House of Deputies. The Bureau of Investigation received, also, a letter from the Dean of the Medical Faculty of the Royal Hungarian Pazmany Peter University of Budapest, stating that Dr. Teglassy was never assistant professor in that institution and was never in charge of its cancer research work. It appears that Dr. Teglassy did serve as an unsalaried junior in the dermatological clinic for two years and as a salaried junior for the next two years. In the last year of his service he had the title of unpaid assistant, and for a time it was his duty to look after the servants, nurses, household and kitchen. Obviously, the attempt on the part of Adler to drag in the good name of the University of Budapest is without the remotest justification.

Dr. Szado, the dean, also sent the Bureau of Investigation a letter written by Dr. Teglassy himself, in which he attempts to explain his episode of the Adler treatment. The letter is not convincing. According to Dr. Teglassy some five or six years ago a Mr. Adler visited him and presented him with 'a gelatinoid anti-cancer preparation' which, according to Adler, was being used with very good results in the United States. As Dr. Teglassy had some cancer patients in his private practice he accepted some of the Adler preparation, sent some of it to a chemical laboratory and having been informed that the laboratory could not determine the exact composition of the preparation but that it was an extract of vegetable material and non-poisonous, he administered the preparation to his patients who he claimed after a few months use reported a certain sedative effect. Dr. Teglassy stated further that the Mr. Adler who brought the preparation asked him to give a few lines telling that the preparation had shown a good effect so.

On my prescription blank I gave him a few lines in which according to my best recollection I wrote that the offered gelatinoid vegetable preparation has been used by my patients suffering with cancer and after its use they have felt a certain sedative effect.

Dr. Teglassy's letter says further that a few months after this the Adler person disappeared, and having no more of the Adler preparation, he (the doctor) was unable to continue experimenting with it. Dr. Teglassy expresses astonishment to learn that his name is being used in an advertising campaign in the United States and believing it to be a misrepresentation he would protest energetically to the American legation that the use of his name be stopped. Dr. Teglassy closes his letter with the acknowledgement that he did not administer the Adler preparation in the University Clinic but only in his private practice.

Of practical interest to the sufferer from cancer is a report by Dr. Ira I. Kaplan, Director of the Division of Cancer, Bellevue Hospital, New York City, who tried the Adler treat-

ment in three cases which had been selected by medical director Poulin as being most likely not to show harmful results Dr Kaplan reported last fall 'We gave his treatment as he directed it. All three patients died horribly and miserably. In two other cases treated under Dr Kaplan's supervision, both died.

Correspondence

"TREATMENT OF BURNS WITH GENTIAN VIOLET"

To the Editor—In the article entitled 'Treatment of Burns with Gentian Violet' (THE JOURNAL, April 22, p 1219) Connell Fatherree, Kennedy and McSwain report good results in the treatment of five patients with from 5 to 9 per cent surface area involvement, with 1 per cent gentian violet in a tragacanth jelly base.

In THE JOURNAL, April 16 1932 V P Blair W G Hamm and I reported the use of a 5 per cent sodium chloride jelly in the care of burned patients 'Since March 1930 we have used as a dressing a water-soluble jelly to which has been added from 2 to 5 per cent sodium chloride this has proved satisfactory in many cases' we stated, and in a footnote, 'Besides the present strength of 5 per cent sodium chloride, the following ingredients have been used 2 to 5 per cent magnesium sulphate, 2 per cent gentian violet, thymol, eucalyptol, and 2 per cent sodium chloride.'

In the usual case we have felt that the sodium chloride jelly would suffice and have been a little prompted in the matter by the troublesomeness of the staining of the gentian violet and its prolonged evidence. However, in some badly infected cases gentian violet may prove to be an effective agent and we have had apparent success with it on some infected skin grafts when other care seemed to fail. The saline jelly has somewhat the effect of a hypertonic wet dressing and we have used it in several types of infected wounds.

Connell and his associates state that no contraction scars remained in any case but it is undoubtedly true that if the full thickness of the skin is completely lost over a large area there will be scar deformity if spontaneous healing is awaited, regardless of how the wound is treated.

J B BROWN, M.D. St Louis

'SAFETY PIN IN VAGINA OF CHILD'

To the Editor—In THE JOURNAL, April 15 appears an interesting account of a safety pin in the vagina of a 4 year old child whose hymen was imperforate. The author Dr Nixon, supplements his communication with a list of similar cases culled from the literature. May I add another? In the case of a child, aged 2½ years seen by me about ten years ago a mucopurulent vaginal discharge had persisted for six months in spite of treatment with antiseptic and astringent douches and instillations by a well known pediatrician who had regarded the condition as a benign vulvovaginitis as the smears were negative. Under this therapeutic regimen the condition would ameliorate and increase and during one of these remissions the child was brought to Atlantic City. After arrival here a sharp exacerbation occurred. When I saw the patient examination disclosed the hymen imperforate except for a small opening in its upper half. On the passage of a probe through this aperture, well into the vaginal cavity, its end came in contact with some hard metallic body. The hymenal opening was then enlarged and by forceps a closed, blackened safety pin, about 2 inches long was easily removed. In a few days the discharge ceased, without further treatment. No adequate explanation could be found as to how the pin

gained entrance into the vaginal canal although it might possibly have been introduced by a nurse, discharged by the mother some months previous, because of misconduct.

D J MILTON MILLER, M.D., Atlantic City, N J

PORTRAYALS OF DISEASE IN FICTION

To the Editor—In the April 29 issue of THE JOURNAL, Dr Phillip E. Rothman cites an instance of the portrayal of the symptoms of a disease in a fictional character appearing before the malady was systematically studied and recorded authoritatively in medical literature, and quotes the character Joe, the fat boy, in Dickens's Pickwick Papers, who was a victim of narcolepsy. May I be permitted to point out another character by the same author that showed sharp power of observation by the writer? In 1848 Dickens in Dombey and Son, chapter XXXVII, capably described the last illness of Mrs Skewton. His delineation of her speechless state, her staring at the ceiling, the making of inarticulate guttural sounds in answer to questions, well depict the symptom complex of hemiplegia. The gradual recovery of some motion in the right hand though not of speech, shows fidelity to nature in a remarkable degree, particularly admirable when emanating from the pen of a nonmedical writer.

In 1861 (thirteen years later) Paul Broca published the memoir wherein he propounded that aphasia is associated with injury to and consequent inaction of the posterior portion of the third frontal convolution on the left side of the brain. This area is now universally known as Broca's space. Curiously enough, the scholarly Dr Oliver Wendell Holmes was not clearly informed regarding the circumstances, for in the course of an address delivered before the Phi Beta Kappa Society of Harvard University, June 29, 1870 he said "A particular spot has been of late pointed out by pathologists not phrenologists as the seat of the faculty of speech. I do not know that our sensations ever point to it."

J A HAGEMANN, M.D., Pittsburgh

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address but these will be omitted on request.

USE OF POISON IVY ORALLY AND PARENTERALLY IN DESENSITIZATION

To the Editor—Kindly discuss the efficacy of poison ivy extracts used hypodermically in cases of dermatitis venenata and the use of tinctures by mouth in these conditions. Are there any serious bad effects from these injections? Kindly omit name.

M.D. New York.

ANSWER.—The idea that chewing poison ivy leaves has a value in preventing dermatitis is a time honored one. Schamberg in 1916 and 1919, advocated the use of

Tincture of rhus toxicodendro	1 cc.
Alcohol	5 cc.
Syrup of orange to make	100 cc.

One drop of this to be taken in half a glass of water half an hour after a meal, two drops in the same way after the next meal and so on, increasing one drop with each dose until twenty-one drops were taken. After this the dose to be a teaspoonful after each meal throughout the season. Clinical reports on the method were encouraging, many patients stating that after taking the treatment they had been exposed to poison ivy without suffering dermatitis though highly susceptible previously. For cases of dermatitis he advocated the same treatment, except that the dose was to be increased two drops at a time up to eighteen then a teaspoonful dose until the attack was ended. The dose of tincture in this plan is small, the maximum not over 0.05 cc.

Strickler, in 1918 advocated for prophylaxis daily hypodermic injections of an alcoholic extract of poison ivy leaves from 0.3 to 0.5 cc., for from three to five days and then the adminis-

tration of the same extract by mouth. He and many others reported good results.

Krause and Weidman (Ivy Poisoning, *THE JOURNAL*, June 27, 1925, p. 1996) reported a scientific test of this treatment. They found, by testing the sound skin ten of twenty volunteers immune, but when they made the patch tests on irritated skin, only four proved immune. They found that repeated tests on the same area of skin developed no immunity, except to accelerate the appearance and disappearance of the eruption, which was just as severe on the fifth test as on the first.

After treatment for ten days by the Strickler method, retesting showed that no immunity had been developed, but rather an increased irritability of the skin and pruritus and which they ascribed to the action of the toxin, unchanged, being passed by the bowel.

Spain and Cooke (Studies in Specific Hypersensitiveness, *J. Immunol.* 13 93 [Feb.] 1927) made a thorough study, producing a stable alcoholic extract and testing by patch tests with varying dilutions of it. Mouth treatment was used in a few cases but was often unsatisfactory because tedious and frequently forgotten. For the first hypodermic injection they used 0.1 cc. of the highest dilution that produced vesiculation in the patch test. They then increased the dose according to the sensitiveness of the patient. They gave the injections once a week for four or five weeks, then once in two weeks for three or four times, and then once a month for the rest of the season. Although 95 per cent of their patients reported benefit, the patch tests revealed no lessening of skin susceptibility.

Andrews (Diseases of the Skin, Philadelphia J. B. Saunders Company, 1930, p. 314) reports coma lasting for twelve hours following the customary drop doses of the tincture of rhus toxicodendron.

Templeton (Untoward Reactions Following Toxin Treatment for Dermatitis Venenata, *Arch. Dermat. & Syph.* 20 83 [July] 1929) reports two types of reaction to the injection of the toxin: local urticaria about the site of injection and widespread urticaria in small wheals at times becoming confluent to form large patches and sometimes mixed with vesicles like dermatitis venenata. Both these were accompanied by intense pruritus. In spite of the experimental work of Krause and Weidman and of Spain and Cooke, Templeton believes that the toxin method is better than the simple soothing method of treatment. He advocates the oral method of Schamberg for mild cases and for desensitization but in severe cases he still uses the injections, beginning with 0.1 cc. and increasing 0.1 or 0.2 cc. each day.

A number of preparations for the injection treatment of rhus dermatitis are included in New and Nonofficial Remedies but no preparation for the prevention of rhus poisoning has been accepted by the Council on Pharmacy and Chemistry.

THYROTOXICOSIS WITH POSITIVE WASSERMANN TEST

To the Editor—A woman aged 55 is suffering with mild thyrotoxicosis. She has what appears to be an adenomatous enlargement of the thyroid. The heart is normal but rapid. The blood pressure is 160 systolic, 85 diastolic. She has a three plus Wassermann reaction. Would neocarsphenamine be contraindicated? What antisyphilitic treatment would be advisable in view of the thyroid symptoms? No basal metabolism test has been made. Kindly omit name.

M D. New York.

ANSWER—The interpretation of a three plus Wassermann test, especially in a metabolic disease such as thyrotoxicosis, may be difficult. In general, results less than a frankly positive or four plus Wassermann test should be discarded in the absence of supportive clinical evidence of syphilis. A careful history regarding the possibility of venereal infection, and a meticulous neurologic and cardiovascular examination, may disclose additional evidence suggesting that the patient may be syphilitic and supporting such a diagnosis. Under any circumstances the Wassermann test should be repeated, certainly in the same laboratory as well as in others, and the physician should know these laboratories since technical errors in the performance of the test are not uncommon.

The diagnosis of toxic goiter should be established beyond any reasonable doubt. Properly executed tests of the basal metabolic rate, repeated on several occasions, would serve a valuable purpose not only in establishing a diagnosis of thyrotoxicosis but also in estimating the effect of management.

Obviously, in the instance cited, several possibilities must be considered. If the correspondent is convinced that the condition is hyperthyroidism, the chance of the patient's having concomitant syphilis is unlikely if the sole evidence of syphilis is the three plus Wassermann test. If, as an outside chance, she really has syphilis, the possibility of the thyrotoxic symptoms being entirely on a functional basis and not due to true thyro-

toxicosis should be kept in mind. If on repeated Wassermann tests in this and other laboratories the reaction is still found to be three plus, a therapeutic trial on antisyphilitic medication should be tried. There can be no harm in carrying out the usual antisyphilitic regimen in thyrotoxic patients including the giving of neocarsphenamine if so desired, provided potassium iodide is at least temporarily withheld. Iodine preparations of all kinds would modify the effects of true hyperthyroidism and might in this way obscure the diagnosis.

If the conclusion is finally reached that the patient is thyrotoxic as well as syphilitic, a definite regimen of first treating her thoroughly for syphilis, including the administration of potassium iodide and, second, when the syphilis is finally under good control and the thyrotoxicosis is under iodine control, subjecting her to a subtotal thyroidectomy at the hands of a good surgeon experienced in thyroid work should be followed. The danger of such a procedure under the conditions mentioned and in the hands of an experienced surgeon should be slight and the probability of effecting a complete control should be very good.

FEVER IN PNEUMOTHORAX

To the Editor—What is the cause of the rise of temperature in a pneumothorax spontaneous or induced? Please omit name.

M D. England.

ANSWER—Rise of temperature in artificial, or induced, pneumothorax may result from several causes.

1 A compression toxemia, due to the rapid absorption of toxins incidental to the compression of abscessed cavities or other inflammatory matter within the lung.

2 Infection of the pleura, which may cause a rise in temperature within twenty-four to forty-eight hours after the institution of pneumothorax or any one of its refills, owing to such infection being introduced from the outside by way of a contaminated needle or through contamination of the needle, which may puncture the visceral pleura and pick up an infection in the lung tissue.

3 The development of fluid in the pleural cavity, constituting a hydropneumothorax. This occurs in about 50 per cent of the patients within one year of the institution of such therapy. In many instances there is a resorption of such fluid without deleterious results. In other instances it may tend to recur and may require removal by aspiration, especially if it reaches a level of approximately the third rib or fifth dorsal spine.

4 The lighting up of a tuberculous process in the other lung or the establishment of a new metastatic focus of tuberculous disease in the good lung.

In spontaneous pneumothorax there are principally two types.

1 The idiopathic type, usually the result of trauma to the chest wall, or the spontaneous rupture of a superficial bleb during exertion. Only rarely will there be a febrile reaction in this type and that usually is associated with infection and the development of pleural exudate.

2 The type associated with the rupture of a subpleural caseous tubercle into the pleural cavity. This is a most serious condition and but few patients who suffer it live longer than one month. The febrile rise here is due to a definite infection of the pleural cavity, usually resulting within twenty-four hours in a hydropneumothorax and followed immediately by a pyopneumothorax. In this type a compression toxemia may also be a factor in a febrile rise.

NIGHT SWEATS

To the Editor—What are the causes of nontuberculous night sweats? The patient is a married woman aged 39. The only significant feature in the history was lobectomy for nontoxic goiter in 1912 and 1926. The sweating always occurs at night and is confined to the upper limbs, head and neck, from the head to about the tenth dorsal vertebra. There is also an underdevelopment of the muscles of the right arm and right side of the face. The muscles of the right side have been weak for the past twenty-four years. This side goes into a myoclonus at night or when the patient is tired and is associated with a feeling of cold and fatigue. Please omit name.

M D. England.

ANSWER—A nontuberculous infection, either localized or general, or thyrotoxicosis, may cause night sweats. In this instance a careful examination to exclude the possibility of harbored infection, and a basal metabolic rate determination under controlled conditions should be conducted. The fact that this patient has been subjected to lobectomy for nontoxic goiter on two previous occasions should arouse the suspicion that the thyroid may be responsible. It is often difficult to make a certain diagnosis of chronic low grade hyperthyroidism. Tachycardia, a tendency to an unstable nervous status, a

moderate increase in the basal metabolic rate, and finally the beneficial response to a therapeutic trial on iodine would support a diagnosis of hyperthyroidism. The symptoms of thyrotoxicosis in nodular goiter may be bizarre and individual symptoms such as sweating, in a given case may be out of all proportion to all other manifestations. Sweating at night, such as described, is a frequent observation in thyrotoxicosis and may even be unilateral. Partial thyroidectomy in nodular goiter is frequently inadequate in controlling hyperthyroidism. A very small nodule that has been left intact may be sufficient to cause persistence of symptoms.

The neurologic manifestations mentioned are probably on an entirely different basis, however, myoclonus may be aggravated by a hyperthyroid state.

If, on study, a persistent low grade hyperthyroidism can be demonstrated to be present the patient should probably be subjected to a third and more radical subtotal thyroidectomy at the hands of a surgeon experienced in thyroid work. Operative intervention, however, should be preceded by three or four weeks on iodine therapy.

HEMATURIA IN PREGNANCY

To the Editor—I should like some advice about the following case. The urine of a woman four months pregnant is apparently entirely blood. Nothing else is distinguishable on urinalysis. She tells me that in the last three months of a previous pregnancy she experienced a similar condition. Her blood pressure has fallen from 120 to 110 systolic in the last two weeks. There is no apparent abdominal pain although she is very weak and the hemoglobin is 70 per cent. If she stays on an exclusive milk diet the urine remains clear but if she eats so much as a crust of bread the condition recurs. At present it will not return clear. Please omit name.

M D Pennsylvania.

ANSWER.—There is not sufficient information given on which to base a diagnosis. The appearance of large quantities of red blood cells in the urine during pregnancy is not a common occurrence. This is especially true when no other symptoms and urinary abnormalities are present. The causes are not essentially different from those which occur in the nonpregnant woman. Essential hematuria has been described but with the perfection of methods of urologic diagnosis the number of cases of hematuria without discoverable cause has diminished. Calculus and infections including tuberculosis, papillomas, tumors of the bladder and kidney, and nephritis would all have to be considered. There are three conditions that could easily be aggravated by the pregnancy and might cause a hematuria with relatively few symptoms: a toxemia, varicosities, and hydro-ureter with hydronephrosis.

The bleeding and coagulation time should be tested to rule out a hemorrhagic diathesis and, of course, a complete blood examination should be made to make sure that none of the diseases of the blood are present.

A cystoscopic and roentgenologic examination would doubtless be required to clarify the diagnosis. The treatment naturally would vary with the diagnosis. If facilities are available for making these examinations they should be done. Bland diet with abundant fluids if there is no edema keeping the lower bowel empty good position of the uterus determined by examination, and exaggerated Sims and knee-chest positions might all be advantageous. Iron should doubtless be administered to combat the tendency to anemia.

TRANSFUSION OF CITRATED BLOOD

To the Editor—I am having some difficulty with the indirect method of blood transfusion using citrated blood in the procedure. I use 50 cc of sodium citrate to 450 cc. of donor's blood. I keep this citrated blood as near body temperature as possible while in the graduated cylinder used for transfusion. When there is only about 15 cc of the citrated blood left in the cylinder I add about 50 cc. of physiologic solution of sodium chloride. I have been getting a jelly like coagulation following the addition of the saline solution. What I want to know is: Why do I get this coagulation? As the transfusion is a success the last procedure of putting the saline solution into the left citrated blood which causes the coagulation is what is giving the trouble. Is the amount of saline solution to the amount of blood citrated overbalanced? I am using Lilly's ampules 50 cc. also Swan Myers and Sharp & Dohme Normal Salt Tablets number 2 four tablets dissolved in 1 liter of water.

ROBERT L. CARSON, St Joseph Mo

Pharmacist Missouri Methodist Hospital

ANSWER.—Sharp and Dohme tablets number 2 contain sodium chloride calcium chloride and potassium chloride. The additional calcium contained in these tablets disturbs the proper equilibrium between the sodium citrate and the normal blood calcium which is responsible for the fact that the blood remains fluid. If physiologic solution of sodium chloride is used, which contains 0.9 per cent sodium chloride but no calcium, the phenomenon that is described will not occur.

Illinois January Examination

Mr Paul B. Johnson, superintendent of registration, Department of Registration and Education, reports the written and practical examination held in Chicago, Jan 17-19 1933. The examination covered 10 subjects and included 100 questions. An average of 75 per cent was required to pass. Forty-four candidates were examined, 42 of whom passed and 2 failed. The following colleges were represented:

College	PASSED	Year Grad	Per Cent
Chicago Medical School	(1932)	79	81*
Loyola University School of Medicine	(1932)	81*	81*

Nevada Reciprocity Report

Dr Edward E. Hamer, secretary, Nevada State Board of Medical Examiners, reports two physicians licensed by reciprocity with other states, Feb 6, 1933. The following colleges were represented:

College	LICENSED BY RECIPROCITY	Year Grad	Reciprocity with
California Medical College	(1885)		California
University of Oregon Medical School	(1918)		Oregon

Book Notices

Annual Reprint of the Reports of the Council on Pharmacy and Chemistry of the American Medical Association for 1932. With the Comments That Have Appeared in The Journal. Cloth. Price \$1. Pp 104. Chicago: American Medical Association 1932.

The successive volumes of these collected reports are designed to give permanent form to the Council's consideration not only of those products which have been rejected by the Council but also of those which show promise but which are not yet ready for general use by the medical profession, as well as those which stand accepted but in regard to the status of which there has arisen a question that needs clarification. The second and third categories are called, respectively "preliminary" and "special" reports, and these are often the most interesting features of the book. Certainly this is true in the case of the newly issued volume of 1932 reports.

The preliminary report on Thorotrast, a colloidal thorium dioxide preparation proposed for use in retrograde pyelography and for roentgen visualization of the liver and spleen by intravenous administration, is an excellent example of this class of reports. The articles on Nirvanol and Triethanolamine are also interesting and timely preliminary reports. Among the "special" reports are those on sulpharsphenamine and mercuriochrome which are of particular timeliness and effectiveness. Each report clarifies the present status of the drug concerned—the former on the basis of a questionnaire circulated among leading syphilologists, and the latter on the basis of independent bacteriologic investigation, done by consultants of the Council. Among the reports on products definitely rejected for inclusion in New and Nonofficial Remedies, those of particular interest to physicians are Amertan, an unoriginal mixture of tannic acid and merthiolate in a water soluble jelly, marketed under a proprietary, uninforming name; Antiopin, a mixture of indefinite composition offered under a nondescriptive therapeutically suggestive name and marketed in a way that may foster the drug habit; Eubetin, another insulin substitute for oral administration marketed under a proprietary uninforming,

name with unwarranted claims; Ferro Copral, a mixture of saccharinated ferric oxide, manganese citrate and copper proteinate proposed for use in the treatment of pernicious anemia and marketed under a proprietary name with unwarranted therapeutic claims; Hepatex P A F, a liver preparation proposed for intravenous use and marketed under a proprietary and insufficiently descriptive name with no satisfactory evidence of the safety of its recommended intravenous use; Bi So Dol, an unscientific "alkalinizing" mixture offered under an uninforming proprietary name with exaggerated and unwarranted claims of therapeutic usefulness; Gan-Aiden, consisting mainly of the well known ethyl aminobenzoate (benzocaine), a preparation of undeclared composition marketed under a noninforming, proprietary name, Myodin, Subidin and Sanguodin, unscientific preparations of iodine marketed with unwarranted claims and indefinite, incorrect statements of composition, under proprietary uninforming names, and Tonikum Roche (now Elixir Arsylen Compositum-Roche) a "shotgun" proprietary "tonic" marketed with misleading therapeutic claims.

This volume should be on the shelves of all progressive physicians, pharmacologists and students. It is a convenient and compendious guide to the latest critical thought in pharmacology and therapeutics.

Kurzes Handbuch der Ophthalmologie. Herausgegeben von F. Schiele und A. Brückner. Band II. Physiologie. Optik. Untersuchungsmethoden. Bakteriologie. Bearbeitet von A. Brückner, W. Comberg und anderen. Paper. Price 125 francs. Pp 1079 with 630 illustrations. Berlin: Julius Springer 1932.

Within the appointed time has appeared the final volume of the so called Short Handbook of Ophthalmology, concluding a monumental work that is undoubtedly the most valuable reference series in ophthalmology that has ever appeared. This statement is made advisedly, for although the Kurzes Handbuch has not the voluminous, the elaborate bibliography or the discussion of case reports that characterize the Graefe-Saemisch Handbuch der gesamten Augenheilkunde, it has the advantage of being brought down to the present and has been completed within a reasonable time. The cost is high, averaging about 140 marks per volume, but the value is there. This volume, labeled the second, contains the following divisions: Physiology of the Nutrition and Circulation of the Eye, by Otto Weiss of Königsberg; Morphologic Changes in the Retina Under the Influence of Light, by Karl vom Hofe of Cologne; The Visual Purple and Chemical Changes in the Retina, by Rudolf Dittler of Marburg; Electrical Processes of the Visual Organ, by Arnt Kohlrausch of Tübingen; The Light Sense, by Max Comberg of Berlin; The Color Sense, by Rudolf Helmholtz of Danzig; The Physiology of Optical Perceptions, by Rudolf Dittler of Marburg; Refraction and Accommodation, by Heinrich Erggelet of Jena; The Theory of Spectacles, by Heinrich Erggelet of Jena; The Clinical Methods of Examination, by Arth Brückner of Basel; and The Bacteriology of the Eye, by Max zur Nedden of Düsseldorf. This volume maintains a standard set by its predecessors, in thoroughness of material presented, in completeness of bibliography, and in general physical make-up. The seven volumes form a reference work indispensable to every library and scientific ophthalmologist.

American and Canadian Hospitals. A Reference Book Giving Historical, Statistical and Other Information on the Hospitals and Allied Institutions of the United States and Possessions and the Dominion of Canada. Edited by James Clark Fifeild with the Cooperation of the American Hospital Association. Cloth. Price \$10. Pp 1,000. Minneapolis: Midwest Publishers Company 1933.

This is a reference work giving historical statistical and other information of the hospitals of the United States and Canada. In the development of the work the publisher has had the cooperation of numerous officers of the American Hospital Association, as well as other persons interested in hospital service. The book opens with a brief history of the American Hospital Association, followed by a statement concerning the Council on Medical Education and Hospitals of the American Medical Association, the Department of Hospital Service of the Canadian Medical Association, Canadian Hospital Council, the American College of Surgeons, the Catholic and Protestant Hospital Associations, the American and Canadian Nurses' Associations, the League for Nursing Education and the Association of Hospital Workers. There are also statements about the American Sanatorium Association and

the Association of Record Librarians of North America and the American Occupational Therapy Association. There follow then in geographic order, by states and cities, records of all of the hospitals and sanatoriums in the United States, giving first of all the histories of the institutions, their character, their rates, their staff, their equipment, the trustees, the bed costs, average attendance, training schools for nurses and indeed, practically all the important information that any one might desire. Nothing is said as to the manner in which the information was collected but it is presumed that it was done by the questionnaire method. The book concludes with a series of appendices providing the history of numerous organizations related to the hospital field from every possible point of view. There are, for example, a life of Dorothea Dix and one of Florence Nightingale as well as statements concerning the history of the Commonwealth Fund, the Rosenwald Fund, the Duke Endowment and similar organizations. The book is an exceedingly useful work of reference for any one in the medical field.

Fèvre boutonneuse. Fèvre exanthématique du littoral méditerranéen. Par D. Olmer, professeur de clinique médicale à la Faculté de médecine de Marseille et Jean Olmet, chef de clinique médicale à la Faculté de médecine de Marseille. Collection médecine et chirurgie pratiques no 57. Paper. Price 17 francs. Pp 104 with 10 illustrations. Paris: Masson & Cie 1933.

The authors bring together in this treatise the facts at present known about a type of spotted fever of the Mediterranean littoral, a disease first designated as 'fièvre boutonneuse' by Conar and Bruch in 1910 in Tunis and to which this name was later restricted by the first International Congress of Hygiene at Marseilles. The disease is clinically and immunologically distinct from true typhus fevers (epidemic and endemic types) is transmitted by dog ticks (*Rhipicephalus sanguineus*), and is quite uniformly benign in character. It is a disease of summer occurring in foci in the country from one year to another. The history of the disease is reviewed, its etiology and epidemiology are discussed and a description of the clinical studies is given. There are also chapters on the laboratory observations, nosology, prophylaxis and treatment, and an extensive bibliography. It is an important contribution to knowledge of the typhus fevers.

Indigenous Drugs of India. Their Medical and Economic Aspects. By R. N. Chopra, M.A., M.D., Lieut. Colonel Indian Medical Service. Cloth. Price Rs. 15/- Pp 603. Calcutta: Art Press 1933.

With anticipation of possible surprises one opens this book, having so romantic a title and bearing on its front page Longfellow's

Come Wander with me, she said
Into regions yet untrod
And read what is yet unread
In the manuscripts of God.

One is not disappointed. It is the first book of this kind to be permeated by the critical spirit of modern pharmacology. The author fully understands the herculean nature of the task of attempting to clean out the Augean stable of the ancient Hindu medical lore. He points out that India was really the cradle of the world's medical knowledge, which was laid down most especially in its Ayurveda (2500-600 B.C.), and that there are unmistakable evidences of the influence of the Hindu materia medica on the Greek and Roman and through these on Arabic materia medica. With the conquest of India by the Moslems, the Arabic system was introduced and the Ayurvedic methods were discarded. In other words, this knowledge of Hindu origin, no doubt changed, was reimported into India by its conquerors, and the same thing happened again with the establishment of the British rule. It is freely admitted that, in this process the ancient knowledge has been so much refined and improved that it bears no resemblance to its original source. The author proposes to apply modern methods of extraction and assay, of pharmacodynamic and clinical study to the Ayurvedic materia medica at present discarded by the Western system of medicine though still largely used by the people of India. The research work on indigenous drugs, initiated by the author at the Calcutta School of Tropical Medicine has three main objects in view: to make India self supporting in the production of medicines to discover remedies that might be employed by the exponents of 'Western medicine,' and to develop means of medicinal economy to render the necessary remedies available to the great masses of India

whose economic condition is low. There is no doubt that India, which could supply the whole of the civilized world with medicinal herbs, is at present shamefully exploited by manufacturers of ethical as well as of other proprietary medicines, who in many instances get from India the raw material at a pittance and reintroduce the finished product at an enormous increase in price. Readers in this country will of course, be chiefly interested in the second of the avowed aims and from this standpoint the book merits the attention of progressive pharmacologists and of enterprising manufacturers all over the world.

Neuropathology. The Anatomical Foundation of Nervous Diseases. By Walter Freeman, M.D., Ph.D., D.N.B., Professor of Neurology, George Washington University. Cloth. Price \$4. Pp 349 with 110 illustrations. Philadelphia & London: W. B. Saunders Company 1933.

At last a textbook of neuropathology has appeared that can be unhesitatingly recommended for the medical student. It is concise and written in a simple readable style within the capacity of the medical student to understand. The author has evidently attempted to select the essentials and present them clearly and attractively. The illustrations have been chosen for the same purpose and actually illustrate the text without being so numerous as to confuse the student. One might wish that drawings had been used, but the photographic reproductions are for the most part fairly clear. The common lesions are given the greatest space. The discussion of tumors is in line with the latest pathologic studies. The glossary is useful. The book should be popular with those who must teach neuropathology to medical students.

A Standard Classified Nomenclature of Disease. Compiled by the National Conference on Nomenclature of Disease. Edited by H. B. Logie, M.D., C.M., Executive Secretary, Fabrikoid. Price \$3.50. Pp 702. New York: Commonwealth Fund 1933.

This volume is the outcome of an effort carried on now for several years in an attempt to develop a uniform nomenclature for use by hospitals, health organizations and insurance companies. This nomenclature is supposed to include every disease that can be recognized clinically to avoid repetition and overlapping and to classify the diseases in a logical manner. It is supplemented by an alphabetical index to aid reference. The numbers of the international lists of causes of death are printed in italics after the titles of the diseases to aid comparison of the morbidity and mortality information. Code numbers are supplied to enable the use of punch card systems for tabulation. English terms are employed in preference to Latin and Greek, except as concerns diseases of the skin and eye, in which custom has entrenched Greek and Latin names. Diphthongs are avoided in English terms. Because of the difficulty of classifying certain conditions, such as lumbago, headache, rheumatism, jaundice and asthma, a special supplementary list of such terms is provided in an appendix which thus forms a useful guide to fields for investigation.

The compilers of this book have been familiar with nomenclatures previously prepared by other groups. The volume they have prepared is probably as good as could be developed by any type of organization. It should be given careful trial so that its merits and demerits may be well established before the publication of another edition.

Herzneuosen und moderne Kreislanftherapie. IX Fortbildungs-Lehrgang in Bad Nauheim 16-18 September 1932. Herausgegeben von der Vereinigung der Bad Nauheimer Ärzte. Boards. Price 10 marks. Pp 159 with 20 illustrations. Dresden & Leipzig: Theodor Steinkopff 1932.

The fifteen chapters represent lectures delivered during the course of instruction at Bad Nauheim in September 1932. Some of these chapters have already appeared as articles in medical journals. The subjects are handled by men from various cities in Germany. That the chapters vary widely as to excellence of content as well as manner of presentation goes without saying. One may be sure, also, that the virtues of Bad Nauheim as a suitable place to which to refer patients for the treatment of cardiac disorders are not overlooked. Three of the authors register from this resort. Five chapters deal with cardiac neuoses, six are devoted to the modern treatment of circulatory disorders. Four deal with various topics related, though less intimately, to the main subjects considered during the course.

Medicolegal

When Employee May Reject Employer's Physician

(*Wingate v Evans Model Laundry (Neb)* 244 N W 635)

The claimant, in the course of her employment, undertook to lift a bag weighing 102 pounds. She twisted and strained herself, felt a sudden pain in her abdomen and back, and became faint. After a short period of rest she resumed work, although apparently still partly disabled. Her employer sent her to a specialist in diseases of women who diagnosed her case as a prolapsed uterus second degree traumatic in origin. He insisted on an operation although the employer's regular physician a specialist in surgery advised against it, since he could find no evidence of prolapse. The operation was performed but it gave no relief nor did other treatment administered by physicians in the service of the employer. The injured employee thereupon consulted specialists of her own selection. They found, among other evidences of injury, a fracture of the transverse process of the fifth lumbar vertebra on the left side. The operation wound in the employee's abdomen had closed with a keloid formation—a raised thickened hard scar, tender to the touch and on movement. The patient still suffered great pain on moving and there was tenderness over the injured vertebra.

In the first instance the employee was paid compensation for nine weeks. After a hearing however the compensation commissioner dismissed her claim for further compensation. She appealed to the district court, which awarded her compensation for the services of her own physician who had assisted at the operation and compensation for temporary total disability. The court directed her employer and his insurer to furnish proper medical treatment by physicians selected or approved by her. The employer and his insurance carrier appealed to the Supreme Court of Nebraska.

Where the services furnished by an employer are inadequate or inefficient, it has been held that an employee is justified in changing to his own physician and is entitled to the reasonable costs of such service. *Kelley v Pacific Electric R Co*, 1 Calif 1 A C. Dec. 150. In the present case, said the court, the employee, being still totally disabled having received no benefit from the treatment given her by any of the doctors furnished by her employer and becoming desperate of ever being benefited by them was warranted in selecting other experts to take additional roentgenograms and to make a new diagnosis.

The employer and his insurance carrier contended that the district court erred in holding that the employee was entitled to further medical treatment by physicians to be selected or approved by her. The Supreme Court pointed out however, that an injured workman, while in a hospital or under the care of a surgeon is still in the course of his employment and so continues as long as his disability remains. *Ross v Erickson Construction Co* 89 Wash 634, 155 P 153 L R A 1916F 319. Moreover when an employer or an insurance carrier employs a physician for his injured employee and that physician makes a wrong diagnosis, the disability resulting from that erroneous diagnosis is compensable. *Johnson v Pacific Surety Co* 1 Calif 1 A C Dec 560. A patient subjected to a painful and unnecessary operation, by reason of which her disability is increased and tenderness pain and weakness continue is to be allowed compensation.

The Supreme Court however for other reasons, reversed the decision of the district court in favor of the employee, and remanded the case.

Workmen's Compensation Acts Freezing of Foot Afflicted with Buerger's Disease—The trial court found that the freezing of Wright's toes and foot resulted from the combined effects of Buerger's disease and of the wet, muddy, slushy and cold condition to which the foot was exposed and that this was an accident arising out of and in the course of his employment, and entered judgment in his favor. His employer appealed to the Supreme Court of Kansas. This court recognizes, said the Supreme Court, that peculiar circumstances make an event an accident when under ordinary circumstances it might not have been so, that an injury may be an

accident in the case of a person suffering from a disease, although it would not have been sustained by a perfectly healthy individual, and that if an existing disease is aggravated by accident the resulting injury is compensable. The court could find, however, no element of an accident conspicuous in this case. The climatic condition was normal for the season when the injury occurred and it was normal for the top of the ground to freeze and thaw. There was no storm flood or other sudden or unusual event. It would not have been an accident under the circumstances for a foot or a hand not sufficiently protected to freeze. While there are cases in other jurisdictions that hold freezing to be an accident, in most of them the freezing seems to have occurred under very unusual and peculiar circumstances. Such cases however failed to convince the Kansas court that the freezing of a diseased foot under the circumstances of this case constituted an accident within the meaning of the law. The award of the trial court in favor of the workman was therefore reversed.—*Wright v Keith (Kan)*, 15 P (2d) 429.

Value of Physician's Services Provable by Lay Evidence—A layman may be competent to testify as to the reasonable value of services of a physician, but this rule is based on the fact that the witness' qualifications to do so must appear in the record. *Millard v Northwestern Mfg Co*, 200 Iowa 1063, 205 N W 979.—*Wood v Branning (Iowa)*, 244 N W 658.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American Journal of Cancer, New York

17:293-587 (Feb.) 1933

Suggested Methods for Standardization of Carcinogenic Activity of Different Agents for the Skin of Mice. C. C. Twort and J. M. Twort. Manchester, Lancashire, England.—p. 293.

*Carcinoma of Colon. Its Roentgenologic Manifestations and Differential Diagnosis. H. M. Weber. Rochester, Minn.—p. 321.

Encephalography in Surgical Lesions of Brain. Report of Fifty Consecutive Cases. W. J. Gardner and B. H. Nichols. Cleveland.—p. 342.

Roentgenographic Findings Associated with Tumors of Spinal Column, Spinal Cord and Associated Tissues. J. D. Camp and A. W. Adson. Rochester, Minn. and J. J. Shugrue. Washington, D. C.—p. 348.

Roentgenology of the Pharynx and Upper Esophagus. H. K. Pancoast. Philadelphia.—p. 373.

*Sympathetic Tumors of Adrenal Medulla. Report of Four Cases. E. Scott and Marguerite G. Oliver, Columbus, Ohio, and Mary H. Oliver.—p. 396.

Postmortem Observations of One Hundred and Eighteen Carcinomas of Large Bowel. W. G. Harding, 2d and F. D. Hankins. Los Angeles.—p. 434.

Cultural Characteristics of Cysticercus Cysts and Two Cysticercus Tumors. W. Mendelsohn. Baltimore.—p. 442.

Carcinoma of Colon.—Weber points out that success in the treatment of patients afflicted with carcinoma of the colon will be advanced with the development of refinements in diagnostic methods. It is possible that a great many of the failures in treatment are attributable to the late stage at which the lesion was first recognized. Roentgenologic methods make it possible to recognize carcinoma in its early stages, often before there is adequate clinical evidence for suspecting its presence. The disease must be identified early in its course to permit the earliest possible institution of the therapeutic procedures indicated. Any changes in intestinal habit, evidenced by irritability, mucous diarrhea, alternating periods of constipation, localized pain and tenderness which do not tend rapidly to disappear, not to mention tumefaction, anemia and obstruction, are indications for a most thorough roentgenologic investigation of the intestinal tract. It is not out of place to recommend that this investigation be included in the routine yearly examinations. Such measures are necessary to increase the operability of the malignant lesions encountered, and simultaneously will offer much more reasonable hope for satisfactory end-results.

Sympathetic Tumors of Suprarenal Medulla.—Scott and his associates present 158 cases of tumors with their origin in one or both suprarenal medullas, collected from the literature and classified on the basis of their structural differentiation. They also report four cases of sympathicoblastomas from their laboratories. The Pepper type of tumor of the suprarenal medulla (1) may originate in the right, the left, or both suprarenals, (2) frequently is congenital, (3) occurs in the cases reviewed at an average age of 15 months when primary in both suprarenals, 2.25 months when primary in the right, 15 months when in the left, (4) was found in thirty cases from the literature and in one of the authors' cases, and (5) is found only in the completely undifferentiated class of tumors. The Hutchison type of suprarenal tumor (1) was found in thirty-eight cases from the literature, (2) may originate in either suprarenal but was not found when the tumor was primary in both, and (3) occurs at an average age of 85 years when primary in the left, at 3.5 years when primary in the right suprarenal. Both Pepper and Hutchison tumors when originating in the right suprarenal occur at earlier ages than do those in the left suprarenal. The younger the patient, the more undifferentiated the tumor elements. The more undifferentiated the tumor, the greater the number of metastases and

the greater the degree of malignant changes. Tumors with atypical metastases occur, as a rule at older age levels and are more mature in structure. Sex does not appear to be a factor in the incidence of these tumors. The conclusions of Frew as to the relationship of the type of metastasis to the seat of the primary tumor do not seem to be borne out by a study of a larger number of cases. Any attempt at an explanation of the underlying factors determining the type of metastasis is at present theoretical. Whether sympathicoblastomas, especially of the Pepper type, are truly metastatic, or whether the foci are heterotopic in origin has been discussed in the literature. According to Wiesel, rests of sympathetic building cells may occur in early fetal life on the under surface of the liver. It is conceivable that as the liver grows these cells may be carried into the hepatic tissue with the anastomosis of the vitelline veins and be widely distributed with the blood vessels. Matzdorff, also, thinks that the liver tumors are not true metastases but are primary from fetal rests. The distinctly earlier age at which the Pepper type appears might argue for the theory of a systemic origin of this type. However in the records of all types of malignant sympathetic suprarenal tumors and in one of the authors' cases a probable congenital Pepper type, tumor cells were found filling the lymph nodes and blood vessels of both the primary and the secondary growths. This fact is evidence for a genuine metastasis as one means at least of the distribution of the tumor masses.

Septicemia in the New-Born.—Dunham reports thirty-nine cases of septicemia in new-born infants occurring during a period of five years at the New Haven Hospital. The final diagnosis, based on the growth of organisms from the blood, was usually corroborated by clinical, and in many cases by postmortem examination. The commonest organisms found were the streptococcus, the staphylococcus and *Bacillus coli*. Clinically, septicemia due to the streptococcus seemed to differ from other types of septicemia by the absence of jaundice and bleeding, by the less frequent enlargement of the spleen and by the more frequent appearance of cutaneous infections, omphalitis, peritonitis and meningitis. Streptococcus septicemia invariably had a fatal outcome. In the cases of septicemia caused by the staphylococcus or by *B. coli* on the other hand jaundice was a common symptom, occurring in more than half of the cases in the two groups. Bleeding took place in about half of the cases in the staphylococcus group and in about a third of the cases in the *B. coli* group. The spleen was frequently enlarged (in half or more of the cases) in the two groups. Anemia, however, was less common in staphylococcus septicemia than in that caused by the streptococcus and *B. coli*. Infection of the urinary tract was found only in cases of *B. coli* septicemia. Staphylococcus or *B. coli* septicemia was not invariably fatal.

Excretion of Xylose.—Fishberg and Friedfeld describe a renal function test based on the oral administration of xylose. The normal kidney concentrates more than 25 per cent of the xylose in the urine after the ingestion of 1 Gm. of xylose for every 3 pounds of body weight, and the xylose is practically removed from the blood stream within five hours. The functionally deficient kidney concentrates less xylose and retains it for a much longer period in the blood. The kidney function may thus be estimated in the blood of infants when the collection of urine is difficult. Their technic is as follows: After limitation of the intake of fluids from the preceding evening,

specimens of blood and urine are taken in the morning. For every 3 pounds of body weight 1 Gm. of xylose up to a maximum of 50 Gm. is given in lemonade. Specimens of blood are collected at one and a half, three and five hours. Specimens of urine are taken at one, two, five, eight and twelve hours, and then another twelve hour specimen of the urine is taken. Quantitative reduction tests are made on the specimens of urine. Yeast is shaken with ten times the volume of water and centrifuged. The supernatant fluid is poured off and this process is repeated until the supernatant liquid no longer shows any reducing power with a Benedict solution. A 10 per cent solution of this yeast is then made. Oxalated blood, 1 cc. is dropped into 7 cc. of this solution and allowed to stand for two minutes. Two cubic centimeters of tungstic acid is then added and the Folin-Wu determination of reducing substance done.

Resolving Exudates in Pulmonary Tuberculosis.—On the basis of a critical review of the literature and in the light of personal clinical and pathologic experience, Reichle has reached the conclusion that resolving lesions are of three types: (1) simple atelectases, (2) nontuberculous lobar or bronchopneumonias and (3) retrogressive tuberculous pneumonias. The exact relative incidence of the three lesions is not known, but it is probable that the retrogressive tuberculous pneumonias predominate. This is without doubt true for the lesions of long duration that lead to resolution. Since resolution is possible in almost every form of tuberculous inflammation, there is no reason for calling on any unusual mechanism to explain the retrogressive tuberculous exudates. Clinically, the only reliable criterion for the diagnosis of the retrogressive type of tuberculous pneumonias is the course of the disease. This involves the ultimate complete or almost complete resolution of the process. The necropsies heretofore reported have dealt with the stage prior to possible resolution or after resolution was complete, and therefore have contributed little to the solution of this problem. A decisive contribution would be made by repeated biopsy examinations, as in the case of Rubinstein.

Multiple Liver Abscesses Caused by Leptothrix.—Harris reviews the literature pertaining to leptothricosis pathogenic to man and reports a case of leptothricosis in which

multiple liver abscesses were formed, with rupture of one abscess into the base of the right lung and formation of a lung abscess and rupture of another in the left lobe of the liver, leading to the production of pericarditis. The organism was isolated in pure culture from the liver and successfully carried in vitro through many generations. No other organisms were present in the lesions. Experimental work with the organism showed it to be slightly pathogenic for rabbits and guinea-pigs. This organism has apparently never been previously encountered.

Effects of Arsphenamine and Tryparsamide.—Solomon and his associates state that a distinct difference between arsphenamine and tryparsamide is shown by their opposite effects in systemic syphilis and neurosyphilis, in sodoku (rat bite fever) and in malaria. Arsphenamine is more effective in early and late systemic syphilis, presenting skin, mucous membrane and bone lesions, whereas tryparsamide is more effective when the central nervous system is involved. Arsphenamine cures sodoku, whereas tryparsamide does not but, nevertheless it modifies the skin or local lesions as effectively as does arsphenamine. Arsphenamine is a plasmodicide and cures inoculation malaria, whereas tryparsamide has no noticeable effect either on the plasmodia in the blood or on the course of the fevers. The authors therefore conclude that arsphenamine is both a spirocheticide and a plasmodicide, while there is no evidence that tryparsamide has any direct lethal effect on the Spirochaeta pallida, the Spirochaeta morsus-muris or the plasmodia of inoculation tertian malaria. The beneficial action of tryparsamide on syphilis of the nervous system must be founded on some other characteristic. The results of the experiences in sodoku suggest that there is a stimulation to the local tissue which heals promptly with out destruction of the spirochetes in the blood stream. How this stimulation is produced is not at all clear. One may be justified in assuming that, as in the case of the local beneficial action in sodoku, so in syphilis of the central nervous system, tryparsamide has a local action within the local areas of the nervous system.

Treatment of Syphilis with Hyperpyrexia.—Epstein and Paul treated a group of twenty-eight patients with various forms of syphilis of the central nervous system by means of hyperpyrexia produced by diathermy. They used a diathermy apparatus capable of elevating the body temperature to 41.1 C. (106 F). They employed, with some modifications, the technique of Neymann and Osborne. Striking improvement was noted in thirteen patients with tabes dorsalis. The relief of pain was an outstanding feature. Improvement was noted in patients with other types of syphilis of the central nervous system, but this was not as marked as in the tabetic group. Serologic changes did not parallel the clinical improvement. One fatality occurred early in this work. The patient was a man, aged 67, with an extremely demented type of dementia paralytica. He was obviously a poor physical risk, but because of the rapid progress of his dementia his private physician felt the risk justifiable. Death followed the first treatment. His temperature rose to more than 106.8 F. In this patient a secondary rise in temperature occurred three hours after the

current was shut off. His blood pressure was 220/0 five hours before death and 90/0 a few moments before.

Electrocardiographic Observations in Syphilis—Chargin and Paley studied for electrocardiographic changes fifty cases of early syphilis of duration not longer than three months. All the patients were young adults below the age of 35, with the exception of three who were between 35 and 40. Care was taken to exclude all other diseases that might be responsible for cardiovascular changes, such as rheumatism, chorea, hypertension, arteriosclerosis and acute infectious diseases. Thirteen patients, or 26 per cent, had clinical right axis deviation. Three, or 6 per cent, had an index below 10. Five, or 10 per cent, had an index between 10 and 15, and the remaining five, or 10 per cent, had an index over 15. The high percentage of right axis deviation would seem to indicate that it is more than a mere coincidence. It may have some bearing on the syphilitic infection. Further observations are necessary to determine this. Four patients, or 8 per cent, showed definite myocardial involvement, as evidenced by changes in the T wave. One case showed isoelectric T waves in leads II and III, three cases showed definite inversion of the T waves in leads II and III, the last three were associated with definite right axis deviation with an index over 15.

Clinical Significance of Leukopenia—Mettier and Olsan present five cases of severe leukopenia of obscure origin and call attention to the different types of bone marrow reaction occurring in the various cases, namely, aplasia of the bone marrow, depression of leukopoiesis only, hyperplasia of the leukopoietic tissue, and hyperplasia of the erythropoietic tissue. They also report a case of leukopenia associated with lymphangitis of the arm in a woman in whom recovery occurred during the course of the administration of nucleotide K-96. Among the 10,000 case histories of the patients cared for in the University of California Hospital from 1920 to 1931, examination of the blood revealed leukopenia in 1,167, or 11.67 per cent, of the cases. Of the 1,167 cases, leukopenia occurred in 611 females, or 52.4 per cent, and in 556 males, or 47.6 per cent. Leukopenia occurred frequently as a mild manifestation in patients with vague symptoms of one sort or another, such as chronic fatigue, 97 per cent of the cases of leukopenia were classified therefore as benign leukopenia of obscure origin. A table of the frequency incidence of leukopenia is given.

Speech Disorder Following Epidemic Encephalitis—Gordon describes the speech disorder in two patients following epidemic encephalitis, in whom in the beginning of their speech, the tongue rolls, curls and places itself mostly on the right side. The muscles near the angles of the mouth and those of the chin contract more than the other muscles of the cheeks, so that two deep furrows appear on both sides of the mouth. It seems that all the other muscles of the patients' faces remain immobile while the lip muscles function. There was also a tendency for the lower jaw to droop while speaking. The author emphasizes the fact that in addition to an organic lesion ordinarily found in encephalitis, there are other factors of a functional character which may elucidate the nature of the

multiple postencephalitis disorders observed so frequently. An organic lesion alone will not explain its modus operandi in creating all these disorders, especially those of an affective character. Recognition of this principle is of high value in therapeutic endeavors. His two cases present an excellent illustration of this contention, as both patients had difficulties of an affective character at the onset of the disorder and as an outlet from the states of anxiety in which they found themselves, they developed a substitution or a compensation phenomenon in the form of a compulsion neurosis.

Metaphen in Treatment of Ulcers—Trippe gave a 1:500 solution of metaphen orally to patients with symptoms of chronic abdominal distress, in the dose of 4 cc. three times a day with gratifying results. His study includes an analysis of eighty-two patients: twenty-six with gastric and fifty-six with duodenal ulcers. He made complete roentgen studies of twenty-seven of these cases, and confirmed the diagnosis in many cases by a test meal and a microscopic study of the gastric contents. Relief from pain was obtained in practically all cases in an average of three days time. He observed no toxic effects. Complete disappearance of gastric and duodenal ulcers consequent on treatment with metaphen was demonstrated by means of roentgen studies made before and after treatment. He concludes that a possible explanation of the action of metaphen primarily a bactericidal agent, may lie in the part played by infection in the evolution of ulcers of the type considered, as has been recently emphasized by several authors.

Sporadic Benign Rickettsial Fever—An intensely febrile typhus-like disease of short duration was observed to cause a sharply localized group of cases in the west-central part of Illinois during the early part of August 1932. Toomey states that of the eleven known cases, ten were without exanthem. In one case on the fourth day there developed a lenticular ascending, nonhemorrhagic erythematous macular rash resembling the rash of mild Rocky Mountain spotted fever except that it disappeared suddenly with the lysis of the fever. The disease was characterized by an incubation period of about twelve days, sudden onset, abrupt rise of temperature (usually with headache, chilliness and vomiting) and a high continued fever which fell by abrupt lysis after three or four days. A remission of from one to two days was frequently followed by a secondary rise of temperature lasting one day. Constipation and an intense nonproductive conjunctivitis (not accompanied by lacrimation) were characteristic symptoms. Coryza, pharyngeal engorgement and chest symptoms were absent except for an occasional slight dry cough toward the end of the disease. Neuralgic and rheumatoid pains were absent, and the sensorium remained clear. Hyperhidrosis and a regional lymphadenopathy were occasionally observed. There was no mortality. The disease caused a slight leukocytosis due to a relative and absolute increase in the lymphocytes and large mononuclears. Considerable secondary anemia developed. Although the disease was undoubtedly insect borne, a primary sore at the site of inoculation could not be made out in any case. Small erythematous papules, the sites of insect bites were commonly observed to become anemic (white macules) following the termination of the fever. The vector was not identified but there was evidence suggesting that the virus was transmitted by a hymenopteron of the genus *Halictus* (family Halictidae). Agglutination tests against strains of *Proteus* X organisms showed an affinity for the nonindologenic or Kingsbury strains in addition to a moderate affinity for the X strains. The X strains were not significantly agglutinated. There was an inconstant and, at most, a slight increase in the agglutination titer during convalescence. Guinea-pigs were found moderately susceptible to the virus. The disease in guinea-pigs was without a noticeable scrotal lesion and was principally neurotropic, thus resembling epidemic typhus more than certain strains of endemic typhus or Rocky Mountain spotted fever. Inoculation of convalescent guinea-pigs with the virus or Rocky Mountain spotted fever showed that the guinea-pigs were susceptible to the spotted fever virus but appeared to have a partial or group immunity to spotted fever. Preliminary studies indicate that the disease occurs not uncommonly in a mild form, and that it is the cause of some of the cases heretofore called "summer flu" or influenza. Clinically and immunologically, it is necessary to recognize this disease as a separate entity. Serologically, it is related to the diseases having an affinity for the

nonindologenic (Kingsbury) strains of the Proteus X organisms. An approximate clinical similarity to the American mountain tick fever is noted.

*Full Thickness Skin Graft Its Field of Applicability and Technical Considerations J H Garlock, New York—p 259

Fractures of Head and Neck of Radius—From his observation of twenty cases of fractures of the radius over a period of ten years and a review of the literature Bohrer concludes that 1 Fractures of the head and neck of the radius, in children should be treated conservatively unless there is marked displacement of the fragment 2 In cases of marked displacement of the fragment, early operation with replacement of the fragment is preferable to resection 3 If resection is done synostosis of the radius and ulna in the resected area will develop in about 50 per cent. This synostosis occurs several months after operation. 4 In resected cases a stable nonpainful joint may be expected 5 Flexion and extension are seldom limited 6 In resected cases an increased carrying angle always develops, apparently from a lack of growth at the proximal end of the radius 7 In adults, simple fracture with displacement, even if the fracture line involves the articular surface should be treated conservatively 8 In operative cases, resection of the entire head of the radius is the operation of choice. A stable, nonpainful joint, without loss of function, may usually be expected

Localized Tuberculosis of Chest Wall—Meade reports three new cases of localized chest wall tuberculosis and states that there is a striking difference in the number of cases of localized chest wall tuberculosis seen in hospital practice. This can be accounted for by the difference in attitude of the doctors referring patients to surgeons. The process may arise by extension from foci in the lymph nodes of the chest wall or as a hematogenous infection. In order of frequency the bony ribs come first the sternum and soft parts next and the cartilage last. Diagnosis can rarely be made before the cold abscess appears. Examination of its contents will almost invariably settle the question. Treatment must be general and local. Excellent results have been obtained by radical excision well beyond the limits of the involved tissue, removal of all exposed cartilage, and air-tight closure. Drainage should be used only in cases presenting mixed infection.

Full Thickness Skin Graft—Garlock states that the full thickness skin graft has a fairly wide field of applicability. It should be reserved to cover fresh surgical defects and should not be used for granulating wounds. The pedicled skin flap should be used when the local condition requires more underlying tissue than a full thickness graft can supply. There are numerous features in the use of this type of graft which the surgeon must recognize. These include the great probability of necrosis if placed over bare bone or tendon, future shrinkage, changes in color, the development of heavy scars at the edges, and the growth of hair. The author presents an operative technic for full thickness skin grafts which includes complete excision of scar tissue, rigid asepsis, complete hemostasis, the application of firm even pressure over the grafted area, and complete fixation of the part by the use of appropriate splints, and strives to eliminate any form of trauma to the graft. Careful attention to the details of the postoperative care increases the chances of a successful take.

What Do You Think of Physical Medicine? Ethel M Shaul Philadelphia—p 105

Cold Quartz Light in General Practice—Behneman gives a summary of the results of cold quartz radiation in eighty-one cases including sluggish ulcers, burns, endocervicitis, fistulas and rectal ulcers, Vincent's infection (trench mouth), acne, boils and carbuncles, nasal antrum disease with sinus involvement and lesions of the urinary tract. He states the advantages of this type of generator as follows. It is within the wavelength of high germicidal action. It burns at a low temperature with possibilities of application directly to the skin. The official applicator has emission from its entire surface area. The grid lamp may be moved, so that perpendicular ray exposure is possible at all times. Little erythema is evidenced for the radiation produced. There is a constancy of intensity. The handling and use are safe and convenient because of its light weight and detachability. There is usually a relatively low formation of pigmentation. There appears to be little of the red of the visible spectrum. It may be operated while in motion. The temperature at which it burns allows any design of applicator for insertion into body cavities.

Radium in Lesions of Cornea—Lane states that radium has a beneficial and analgesic effect in a number of benign and malignant corneal lesions. Among the benign lesions responding to radium therapy are ectasias, fistulas, keratitis vasculosa, keratitis vesiculosa, keratitis rosacea, tuberculosis involving the cornea, keratitis posterior, and keratitis ulcerosa in its various forms with or without hypopyon. One of the greatest fields of usefulness is in the thinning of leukomas and opacities of the cornea, and the earlier radium is used the better the result. In the malignant lesions radium appears to offer, in many instances, better results than surgery alone as there is less loss of tissue. Considerable judgment is necessary as to the dosage. Frequent biomicroscopic studies are necessary to obtain the best results with radium in benign and malignant lesions of the cornea. The application of radium to the cornea calls for a knowledge of the physics of radium and of the structure of the cornea and of the eye for supportive treatment of the patient, and should be undertaken only by those who are willing to give individual attention to its use.

*Mechanism of Edema T P Sears Denver—p 50

Mechanism of Edema—Sears reviews the various theories of the mechanism of edema. He presents an outline of a new theory of nephritis, which explains edema on the basis of an increased avidity of the tissues themselves whereby water is held in the areas of edema and not presented to the kidneys for excretion. The same situation is claimed for the metabolites. He concludes that edema due to cardiac or nephritic causes is secondary to an imbalance between the filtration and osmotic pressures of the blood stream, plus changes in the permeability of the capillary walls and an increase in the avidity of the tissues themselves for water. The local edema of venous obstruction and the edema of starvation belong in this group. Inflammatory edema and possibly anemic edema is assignable to changes in capillary permeability secondary to traumatism, infection or anoxemia. In all types of edema a normal protein diet is indicated with only such salt restriction as is consistent with the type of edema found.

Urine in Acute Streptococcal Infections—According to Conybeare, colloidal material extracted from the urine of patients suffering from acute infectious conditions associated with B-hemolytic streptococci is capable, in a high proportion of cases, of producing a delayed erythematous reaction when injected intradermally into susceptible subjects. Similar material extracted from the urine of clinically normal persons is by comparison on the same test subjects, relatively inactive as regards the property of producing a skin reaction. Such material from the urine of scarlet fever cases appears to contain the "erythrogenic toxin" (Okell) of the B-hemolytic streptococcus. In five of seven patients with acute pharyngitis, throat cultures showed that hemolytic streptococci of the B type were the predominant organisms. Positive reactions were produced by the extracts derived from four of these five patients. A similar procedure was carried out on the urine of three patients presenting a clinical diagnosis of erysipelas. The extracts obtained in all three cases gave positive reactions. Extracts made from four albuminous urines associated with streptococcal infection gave positive reactions.

Postoperative Hypoparathyroidism—Ellsworth reports a case of postoperative hypoparathyroidism in a Negro woman aged 36 in whom a daily calcium intake of 2 Gm and a limitation of the daily phosphorus intake to 1 Gm resulted in partial relief of symptoms and a rise of the serum calcium and phosphorus. Further limitation of the phosphorus intake to 0.27 Gm daily resulted in further relief of symptoms a slightly higher rise in serum calcium and a fall of serum phosphorus toward normal. Finally, when the patient was at home and exercising, the regimen was ineffective. Raising the calcium ingestion to 5 Gm daily by giving calcium chloride resulted in a return toward normal of the serum calcium, a fall toward normal of the serum phosphorus and a relief of symptoms. In other cases, in which similar ratios of phosphorus to calcium ingested have been tried, beneficial results have been obtained. The author places emphasis on the regulation of both the calcium and the phosphorus intake when treating hypoparathyroidism. The administration of viosterol was followed in his patient by precipitation of active tetany. He has made observations on the effect of the administration of a magnesium salt. Injection of parathyroid extract resulted in a rapid fall of serum phosphorus, a rise of serum calcium and symptomatic improvement.

Hyperproteinemia Associated with Multiple Myeloma.—Wintrobe and Buell observed in the blood of a patient who presented symptoms of coldness, blanching and a peculiar mottling of the extremities, as well as other signs of disturbed circulation a voluminous quantity of a substance which invariably was precipitated immediately on withdrawal of the blood from the body. This material was found to be protein in nature. Necropsy proved that the patient suffered from multiple myeloma. The author discusses the chemical nature of this protein and considers its relation to Bence-Jones protein. Among approximately 500 case reports of multiple myeloma, abnormality in the blood plasma has been found in only eight. Even in comparison with these cases, the author's case seems unique.

Gastric Secretion—Klumpp and Bowie made a total of 357 analyses on ninety-eight subjects under controlled conditions. They noted that in a given individual the secretion of acid in response to a uniform stimulus tends in general to remain within a broad range. Occasional wide fluctuations are, however encountered. One negative histamine test is not conclusive evidence of achlorhydria. The volume of gastric secretion in response to a uniform stimulus fluctuates widely, and no relation between volume and acidity is found. In a series of duplicate analyses, histamine elicited consistently higher values for free and total acid than the Ewald and alcohol tests. The maximum secretion of acid was attained between thirty and forty-five minutes after the injection of histamine. After the Ewald and alcohol tests, the maximum response came at the end of an hour or later. The alcohol test gave higher values for free acid than the Ewald meal, but the latter evoked higher total acidities in duplicate analyses. In duplicate analyses achlorhydria appeared more frequently after the Ewald meal than after alcohol, and least frequently after histamine. Administration of repeated gastric stimuli induced a temporary augmentation of acidity after each, followed by a pronounced falling off, suggestive of a fatigue phenomenon. There was no fundamental difference in the power of the three test meals to elicit this response. Atropine in moderate doses tends to prolong the high level of titratable acidity which ordinarily occurs after histamine. A previous breakfast tends to cause lower acid values and higher total acidities in response to a standard stimulus. Intravenous calcium chloride increases gastric secre-

tion. The authors discuss the theoretical and practical advantages of studying gastric function by means of the histamine stimulus

Treatment of Agranulocytosis—Reznikoff presents the results of adenine sulphate therapy in fifteen uncomplicated cases of agranulocytosis in which recovery followed in eleven of the patients. In severely complicated cases of agranulocytosis or in aleukemic leukemia and aplastic anemia adenine sulphate has not been effective in the doses used in this study. He observed that 1 Gm of adenine sulphate boiled in from 35 to 40 cc of saline solution, given warm intravenously three times daily for at least three days for an adult, is nontoxic, and he suggests that amount as the dose in treating agranulocytosis in adults. This is probably not a maximum dose, but in most patients who responded favorably it was found that with such quantities distinct improvement occurred in the symptoms, in decline of the fever and in an increase of granulocytes within forty-eight hours frequently within twenty-four hours. As much as 10.4 Gm has been given to a patient within seven days with no ill effects.

Inequality of Blood Pressure—Korns and Guinand analyze the data obtained by bilateral brachial pressure measurements in 1,000 normal subjects. What they have arbitrarily designated as a significant sphygmie inequality occurred 439 times in 378 persons. Significant inequalities in pulse pressures appeared in 274 persons, 67 of whom failed to show differences of 10 mm or more between the two systolic or diastolic levels, nearly three fourths of the higher pulse pressures were dextro-lateral. These pressures were measured simultaneously in the two arms, but for all practical purposes consecutive measurement gives equally satisfactory results. Sphygmie inequality without organic disease is probably always transitory and it is reasonably certain that all normal persons manifest it at one time or another. The inequality may involve only the systolic pressures or only the diastolic or both and if the two levels are disparate the inequality may be concordant (both right higher than both left, or vice versa) or discordant (right systolic higher than the left and left diastolic higher than the right, or vice versa). In some persons the higher pressure is irregularly heterolateral in others it appears to be always homolateral. There is no evidence that right-handedness or left-handedness plays any part. The physiology of transitory disparities in brachial pressures is not understood. Sphygmie inequality in the brachial or carotid arteries cannot be regarded as a sign of disease of the aorta or its branches, unless it can be shown to be permanent.

Gastric Secretion in Fever and Infectious Diseases—Chang studied the gastric function by the histamine method in 106 febrile Chinese patients. On the average there was a decrease of the gastric acidity to one third of the normal. The total chloride and the volume of secretion showed a similar but less marked change. The decrease of gastric function was proportional to the height of the fever. Anemia and general physical fitness played no important part. Thirty-three of the 106 patients showed achlorhydria, an incidence of 31 per cent. This is about eight times the normal incidence. Fifty-six patients were reexamined in convalescence. Of these, 90 per cent recovered their normal gastric function soon after the disappearance of fever. The incidence of "permanent" post-febrile achlorhydria was only 5 per cent, which is not much higher than is expected in a healthy Chinese population. Infectious diseases are probably not important causes of gastric anacidity. This definite but transitory impairment of the gastric function cannot be explained on the basis of dilution, nor can it be entirely attributable to duodenal regurgitation. The author suggests a hypothesis in which the pathologic change in the stomach during fever is compared with cloudy swelling in the kidneys. In both instances the functional disturbance tends to be transient.

Studies of Meningococci—Segal states that of the hundred strains of meningococci studied by agglutination and absorption tests, thirty-six were found to be type I, ten type II, twenty type III and twelve type IV. An indirect method of classification was resorted to in five cases. Rabbits were immunized with each of the strains, and the agglutination and absorption reactions of the homologous antisera were studied. Four were found to be of type IV and one of type III. Seventeen strains were found to differ serologically from any of the known types of meningococci. They formed a separate group distinguishable from the Gordon type strains by their agglutination and absorption reactions. The author does not consider the cultural and biochemical reactions of these seventeen strains sufficiently distinct to warrant their being placed apart as a new species. She proposes a fifth type for this group of seventeen strains, since the four existing Gordon types are differentiated purely on the basis of serologic differences. The seventeen strains forming a fifth type of meningococcus were all isolated from the spinal fluids of cases of clinical cerebrospinal meningitis occurring in the Chicago epidemic of 1928 in which all the four known Gordon types were encountered.

Method for Clear Serums for Agglutination Tests—Hall and Learmonth recommend the use of chloroform, ether, benzene or carbon tetrachloride with rennet in securing clear milk serums from goats and cows for agglutination tests with *Alcaligenes melittensis*. The test tubes for the collection of milk samples are corked in the laboratory, each containing a few cubic centimeters of either solvent and a small amount of rennet extract. They are then taken to the dairy and used for the collection of each sample directly from the animal. Each tube is then shaken thoroughly for several minutes to extract the fat. On their return to the laboratory, the tubes are placed in the incubator at 37 C for an hour to coagulate the casein. They are then centrifuged for fifteen minutes at 2000 revolutions per minute to separate the milk serum, which will be found in a perfectly clear deep layer at the top, with a compact curd in the center and the solvent at the bottom. Milk serums collected in this manner may be preserved indefinitely without bacterial growth, owing to the germicidal action of the solvents. There is no interference with the agglutination test for *Alcaligenes melittensis* either by inhibition or by false agglutination. The authors also tested carbon disulphide and tetrachlorethane but found them unsatisfactory, although with both the milk serum separates at the top. But these two solvents definitely inhibit agglutination in the lower dilutions.

Experiments with Bovine Strain of *Alcaligenes Abortus*—Morales-Otero gave three volunteer subjects the infected milk of a cow suffering from infection with *Alcaligenes abortus*. At the end of a six weeks period none of the subjects had at any time shown any symptoms of the disease, and their blood cultures and blood agglutination tests remained per-

sistently negative for *Alcaligenes abortus*. Two other volunteers inoculated one through normal and the other through abraded skin, with the strain isolated from the infected milk presented no symptoms of the disease and their blood cultures were persistently negative for *Alcaligenes abortus*. In the blood of the latter two persons, the author observed a transitory positive agglutination of the organism (in a 1:40 dilution) during the third and fourth weeks of the experiment.

Flatulent Diarrhea Due to *Clostridium Welchii*—Nelson reports local epidemics of flatulent dysentery in which anaerobes of the type of *Clostridium welchii* are indicated as the causal organisms. In the intestinal tract acid readily inhibits their growth. Anaerobes and acidifiers appear to exist in the normal intestine in a fluxional condition of equilibrium with the acid producers dominant. Disturbance of this situation is followed by growth of the anaerobes with certain pathologic consequences. The presence of large numbers of anaerobes of the type of *Clostridium welchii* and *Clostridium sporogenes* in raw market milk is closely associated with the epidemics reported, which indicates a causal relationship between such organisms and the disease. Pasteurization of milk rich in anaerobic flora may accomplish another thing than the safeguarding of health for which it is intended. Milk contaminated with numerous spores of *Clostridium welchii* should not be pasteurized and distributed for consumption unless one can be certain that sufficient acid is produced in the intestine to restrain the development of the anaerobes.

Eosinophilia in Bacterial Reaction Sites—Touart and his associates present the data and results of an investigation into the incidence of local eosinophilia at the sites of early and late skin reactions following the intradermal injection of bacterial substances in twenty-two subjects. They observed that at such reaction sites an increase in the percentage of eosinophil cells in the fluid contents over that found in normal skin was present in most of the patients examined. They conclude that should the observations of their small series of cases be corroborated by future investigations eosinophilia will be recognized as being a regular feature of positive early and late reactions to intradermal injections of bacterial products. So far as eosinophilia indicates the presence of hypersensitiveness, it would appear that the early wheal and the late local reaction are but two manifestations of the same underlying condition namely bacterial hypersensitiveness.

Serum Treatment of Pneumonia—Bullowa reports the conclusions based on experiences in the typing of 1,601 cases of pneumonia observed at Harlem Hospital during the last four seasons. He presents four cases, one illustrating the advantage of giving serum without waiting for the type and showing that even massive invasion of the blood stream may be overcome with an adequate dose of serum one in which inadequate amounts of serum were unavailing one illustrating the difficulty in determining the type and the occasional advantage of lung suction for this purpose and one in which type I invaded blood and pleura with a concomitant infection with type VIb in which recovery occurred after the administration of type I serum and after an empyema due to pneumococcus type I was operated on. The author recommends the early and liberal administration of serum type I and type II in all cases as they are the most frequent invaders. The best treatment of pneumonia requires specific serums of high titer and accurate bacteriologic study. The physician must have this assistance in the treatment of pneumonia if he is not to be handicapped and lose patients he might otherwise save.

Division of Nerves and Tendons of Hand—Koch and Mason are of the opinion that in the surgical treatment of tendon and nerve injuries several technical details are of great importance. First of these is care to insure asepsis. In their judgment nothing in the way of surgical skill accurate apposition of tendons and nerves postoperative care or postoperative physical therapy can compensate for failure to secure healing by primary union. To render such healing as nearly certain as possible the hand and forearm are carefully prepared by thorough and prolonged cleansing with soap and water the afternoon before operation. A sterile dressing is then applied and left in place until the patient reaches the operating room. Just before operation the hand and forearm are painted with a 5 per cent solution of trimetaphenol in 50 per cent alcohol. An area on the abdominal wall from which subcutaneous fat can be obtained is prepared in the same way and if there is a likelihood that tendon grafts will be needed a foot also is prepared. In the operating room sterile linen is applied in such a way that hand abdomen and foot are accessible without shifting the sterile linen once it is in place. Just before the operative incision is made the extremity is elevated for a few moments and the blood pressure cuff applied beforehand inflated to 220 or 230 mm. A bloodless field is indispensable for careful and accurate dissection and suture. Gentleness in the handling of tissue is of paramount importance. This gentleness must be directed not only to the handling of nerves and tendons but to the superficial tissues as well. The authors have used special instruments for holding tendons but have finally come to depend on simple instruments fine tissue forceps with teeth so-called Adson forceps very fine, straight arterial needles for tendon and nerve suture number D Corticelli white silk for the retention suture in the tendon and number A Corticelli black silk for the coaptation suture in the tendon and for nerve suture fine round needles with fine silk for suturing the deep fascia and subcutaneous tissue and fine cutting needles with fine dermal suture or silk for the closure of the skin. In no case in which the preoperative examination left the authors in doubt as to whether recovery was taking place and in which at operation nerve

cnds were found united by a fairly normal appearing spindle of scar tissue were they able to secure a response from electrical stimulation of the nerve in question and, therefore, to determine that resection of the neuroma and suture would not be necessary. In the majority of such doubtful cases, resection of the scar tissue showed smooth connective tissue uniting the nerve ends and forming a complete block to the down-growth of axons. Occasionally the excised section showed on its cut surface a few apparently intact nerve fibers, but in these cases also stimulation of the nerve above the site of injury had failed to produce contraction of the muscles supplied by the nerve in question.

Two Rapid Tests for Pregnancy—Markee tested specimens of urine from 147 pregnant and twenty-six nonpregnant women by the direct and indirect tests for pregnancy based on the modification of the vascular rhythm in endometrial transplants by the presence of relatively large amounts of follicular hormone in the blood stream of the test animals. The direct test is made by injecting the follicular hormone, which has been extracted from 150 cc. of urine, into gonadectomized or nongonadectomized male or female rabbits. Only nonovariectomized female rabbits can be used in the indirect test. Since the intravenous injection of urine from pregnant women induces pseudopregnancy, the animals should not be used oftener than every third week. The diagnosis cannot be made until from seven to eight and a half hours after the injection of the urine. The main advantage of the direct over the indirect test is that the diagnosis can be made forty minutes after the injection or two hours after the specimen of urine has been obtained. Only a limited number of animals are required, since the same rabbit may be safely used every third day. A correct diagnosis of pregnancy by both the direct and the indirect methods was made as early as the forty-seventh day after the beginning of the last menstrual flow. The greatest difficulty encountered in the use of these tests for pregnancy is that the vascular changes observed in endometrial transplants in the anterior chamber of the eye are of two kinds, the rhythmic changes and those that follow fright. The former are arrested in vasodilatation by follicular hormone but the latter are not. The diagnoses of both tests agreed with the patients' clinical histories.

Mercurochrome and Iodine as Disinfectants—Simmons treated skin abrasions, superficial incisions and deep incisions, contaminated with undiluted broth cultures of either *Staphylococcus aureus* or *Streptococcus pyogenes* for various periods of time with solutions of iodine and mercurochrome respectively. Application of tincture of iodine to 151 wounds contaminated with staphylococci resulted in sterile cultures as follows: abrasions, 83.4 per cent, superficial incisions 83.1 per cent, and deep incisions, 31.2 per cent, while its use on 59 wounds contaminated with streptococci resulted in sterilization as follows: abrasions, 75 per cent, superficial incisions 80.9 per cent, and deep incisions 82 per cent. Of the 210 contaminated wounds treated with tincture of iodine, the cultures from 156 or 74.2 per cent were sterile. Mercurochrome used under similar conditions caused relatively little reduction in the numbers of viable test organisms and failed to sterilize any of the 210 wounds. Mercurochrome is comparatively so ineffective in the sterilization of contaminated living tissues that it should not be considered as a substitute for iodine.

Excretion Urography and Sodium Ortho-Iodohippurate—Sodium ortho-iodohippurate, a halogen derivative of a substance normally found in the human urine is proposed by Swick for excretion urography. He has obtained satisfactory urograms in adults with doses varying between 10 and 15 Gm of ortho-iodohippurate dissolved in distilled water in 40 per cent concentration. The injection is carried out over a period of five minutes. The first film is taken ten minutes after the injection, two subsequent exposures being made at twenty minute intervals. Whenever functional disturbances are present, additional films should be taken to determine definitely the absence of visualization or the presence of late visualization. Aside from a slight sensation of generalized warmth there have been no reactions. He has not observed thrombosis at the site of injection. To date he has used the substance in 125 cases having administered 20 and 30 Gm of the substance in some cases. Occasionally transient vomiting occurred with the larger

dose. Children under 13 years of age have received 10 Gm doses without ill effects. A 1 year old child, in whom suitable roentgenograms were observed showed no reactions from a 10 Gm dose. In a 3 year old child receiving 6 Gm. of the substance, satisfactory roentgenograms were obtained. Oral administration in man has given encouraging results. Of fourteen cases, 50 per cent yielded satisfactory urograms. The dose administered by mouth has been between 10 and 15 Gm. dissolved in simple syrup. No reactions have been noted. diagnostic pictures have been obtained 90 and 135 minutes after administration. Further investigations with the oral administration are in progress in the hope of improving the results.

Roentgen Measurements in Pregnancy—Moore describes the recognized methods in vogue today. These are methods based on mathematical calculations alone, methods based on mathematical calculations associated with triangulation and stereoroentgenographic procedures, and scale methods. The two latter types are the ones most commonly used today. The author's method is as follows. A point on the spine at the upper border of the fifth lumbar vertebra is located and a small piece of adhesive plaster is placed over this region. A line drawn from that point through the superior border of the symphysis pubis passes through the plane of the inlet of the pelvis. The patient is placed in a semirecumbent position with the pelvis centered over the cross lines on the surface of the Bucky diaphragm. By the use of calipers the distance from the adhesive tab to the Bucky is determined. The distance from the superior surface of the symphysis to the Bucky is measured with a ruler. The patient is adjusted so that these two measurements correspond. This places the plane of the inlet in a position parallel to the film. The tube is now centered to correspond with the cross lines of the Bucky at a focal film distance of 30 inches. An exposure is made of the pelvis. The patient is then removed from the table and the lead scale placed in the same plane as the pelvic inlet. This is accomplished by using the measurements previously mentioned and with the Bucky running a short exposure is made which superimposes the scale on the film. If one wishes to vary the technic by not having the plane of the pelvis parallel to the film, the procedure then varies and stereoscopic roentgenograms are taken of the pelvis instead of a flat film. The scale in the latter instance is superimposed on one of the stereoscopic films. The reason for adopting this method is that the stereoscopic roentgenograms give one a better visualization of the pelvic inlet, make the parts desired to be measured more distinct and give one a better localization of these points. The pelvimeter consists of a lead sheet approximately 16 by 19 inches in size. This sheet of lead is one sixteenth inch thick and held firmly to a board of the same dimensions by screws placed around the border of the lead plate. The board is approximately half an inch thick and made of basswood. Stiles are placed across each end of the board to prevent warping. Legs are mounted on the board and by the use of thumb screws the pelvimeter can be lowered or raised. The author recommends the following routine: 1. Roentgen pelvimetry on all primiparas as soon as pregnancy is diagnosed. 2. Roentgen pelvimetry on all multiparas with history of difficult labors. 3. Routine care and diet by an obstetrician in all cases when small pelvic inlets or a distorted pelvis is found. 4. Roentgenograms of all obstetric cases just prior to term. 5. Cephalometry, if the latter procedure shows any evidence of disproportion.

Seattle's First Physician. Dr. David Swinson Maynard. J. T. Mason. Seattle.—p. 34

Regional Spinal Analgesia—Vehrs points out that the fundamental principles of regional subarachnoid analgesia are that puncture of the arachnoid may be performed at any desired level, and that the dose of the drug (in this case procaine hydrochloride) necessary to produce sensory block must be

known Since the effective difference between sensory and motor block is from 15 to 25 mg of French procaine hydrochloride, it is easy to determine the proper dosage. With the use of 15 cc of spinal fluid as a diluent, 50 mg of procaine hydrochloride is insufficient to produce an analgesia for sufficient time to perform anything but short time operative and diagnostic procedures, 60 mg is sufficient for dorsal injections and 70 mg will produce complete sensory block with a little superadded motor nerve block. Fear of piercing the cord is unwarranted, and should it occur, it does no harm if small needles and surgical asepsis are used. No injections should be made over the phrenic nerves, because the first dorsal injection site is safer and gives the same analgesic results. Injection of a sensory dose of procaine hydrochloride into the cisterna magna is safer than injections of the same dose in the cervical region, because of the large lake present for the rapid dilution of the drug. The sensory dose for the cistern is much greater than that at any other segment. There are practically no contraindications to this method. No deaths have occurred with this simple technic. This type of analgesia has a great field of usefulness in the cases that require no motor block, and in the patients who have greatly weakened heart muscles and pulmonary or other complications.

Rubber Esophagus—Twenty-three years ago, for an extensive carcinoma, Evans removed the larynx, part of the pharynx, the cervical esophagus and as much of the thoracic esophagus as his fingers could reach behind the sternum. This necessitated a permanent tracheotomy and a permanent gastrostomy. The patient is alive and well today. She takes her food by mouth masticates and swallows it and no onlooker would guess there was anything unusual in the process—but an extra-thoracic rubber esophagus has replaced the normal one. The original empyema tube has been replaced by a curved rubber tube fitted with a flange. The number 9 Jacques catheter originally introduced into the stomach at the time of the gastrostomy has been at various times replaced by rubber tubes of increasing size and eventually has attained its present size, number 15. This too is fitted with a flange, 5 inches from its lower end, and to this tapes are attached the tapes are tied round the abdomen to keep the gastric tube in position.

Extensive Loss of Tibial Diaphysis—Girdlestone and Foley present the case of a boy in whom they performed an operation for bridging a big gap in the tibia after a partial diaphysectomy for osteomyelitis. They used the following technic. Through a long external incision practically the whole length of the shaft of the fibula was exposed and the periosteum incised and reflected. Tracks were then prepared through the soft parts deep to the anterior tibial muscles, vessels and nerves, beginning from each end of the exposed fibular shaft and continued as tunnels drilled with a narrow gouge into the healthiest and strongest part of the tibial metaphysis, the upper one obliquely upward into the upper metaphysis, and the lower one obliquely downward into the lower metaphysis. The right tibia was then exposed and four grafts were cut as follows: (1) an osteoperiosteal graft about $\frac{3}{4}$ inch broad and sufficiently long to cover the whole length of the exposed fibula; (2) a graft about $\frac{3}{4}$ inch broad consisting of cortical and medullary bone, of the same length and (3) two similar but shorter and rather stouter grafts. The two short grafts after being pointed slightly at one extremity were pegged firmly into the tunnels previously drilled in the upper and lower tibial metaphyses. The free ends of these grafts after traversing the oblique tracks in the soft parts ended in contact with the bared shaft of the fibula under the reflected periosteum. The ends were crushed and turned so as to lie in close apposition to the fibular shaft. The long bone graft was then laid along in contact with the shaft of the fibula under the fibular periosteum, and the osteoperiosteal graft was laid over it with its bony surface in contact with the fibular shaft and the three grafts. Both wounds were sutured, and the grafted leg was put into a plaster cast including the knee and ankle joint. Roentgenograms taken ten months after the operation showed great hypertrophy of the fibular shaft, which is beginning to resemble in thickness the tibia of a child of the patient's age.

Osteitis Fibrosa with Hyperparathyroidism—Elmslie and his associates report three cases of generalized osteitis fibrosa with hyperparathyroidism, with an account of the bony lesions as determined by exploratory operations and roentgen examinations, and the results of a chemical investigation of the calcium and phosphorus metabolism. In each of the three cases a tumor of the parathyroids was removed by operation. Tetany resulted from the operation in two of the cases. The diagnosis of generalized osteitis fibrosa depends on the demonstration of generalized rarefaction of the bones in addition to the presence of cystlike areas of rarefaction, cellular tumors of the bones, spontaneous fractures, muscular weakness and wasting, and aches and pains in the limbs. Renal calculi were present in two of the three cases on roentgen examination. An abnormally high level of serum calcium was not always found, even when a parathyroid tumor was present. In the authors' three cases an increased excretion of calcium in the urine was constantly demonstrated. In cases of generalized osteitis fibrosa the presence of hyperparathyroidism should be demonstrated before operation on the parathyroids is undertaken. After the removal of the parathyroid tumor, the level of the serum calcium fell strikingly and calcium was retained by the body or, if retention was present previously, this was definitely increased. An abnormal condition of the phosphorus metabolism was found in each of the three cases, but no consistent relation could be demonstrated between the changes in the calcium metabolism and the phosphorus metabolism, either before or after the removal of the parathyroid tumors. As a result of the removal of the parathyroid tumor striking improvement in general health and strength and cessation of pain resulted in each of the three cases, and no further fractures occurred. A considerable increase in the density of the bones, especially around the cysts and in the cortical bone, was seen from ten to twenty-four months after the operation. In one case the appearance of the skull showed a striking return toward the normal twenty months after the operation.

Resection of Presacral Nerve—Davis describes an operative technic for the resection of the presacral nerve, which is easy and safe to perform, except in the presence of occasional abnormalities, which he gives as he has observed them in twenty consecutive cases. The technic is as follows. When the peritoneum is opened, the abdominal and pelvic organs are rapidly examined and any abnormality is dealt with. This done, the Trendelenburg position is adopted, and the site of

operation is exposed by careful packing off of the intestine on all sides. The three points of Cotte should next be definitely identified by palpation the promontory of the sacrum, the bifurcation of the aorta and the inferior mesenteric artery. The posterior parietal peritoneum over the nerves is gently lifted and snipped with scissors, and the incision is extended upward and downward for an inch or more, exposing the operative field. No attempt should be made to dissect out and excise the individual nerves. Instead, the layer of fibrocellular tissue, in which the nerves run and which lies between the posterior parietal peritoneum anteriorly and the left common iliac vein and the fifth lumbar vertebra posteriorly, should be systematically removed in one sheet, from the left common iliac vein to the right common iliac artery laterally, and from the aortic bifurcation above to the sacral promontory below. A little more than 1 inch of the nerve or nerve plexus is thus excised. It is unnecessary to transgress these limits. The fascia containing the presacral nerves is of a peculiar density and toughness and any doubt of its identity is easily dispelled by exerting firm traction on its proximal cut end. Hemorrhage is usually negligible, coming solely from the tiny vasa nervorum, and is controlled by tampon pressure. The occasionally brisk arterial bleeding from an abnormal vessel is easily seen and clipped. A continuous peritoneal suture of number 90 linen thread completes the intra-abdominal portion of the operation, and the wound is closed in layers.

Chronic Pulmonary Tuberculosis—Wingfield's conception of chronic pulmonary tuberculosis is based on the seven postulates founded on the accepted research work published during the last twenty years. 1 That after the first infection of the human body, with its resulting "primary focus" be this situated where it may the first manifestation, or the early lesion, of the adult type of chronic pulmonary tuberculosis is due to a hematogenous deposit of bacilli obtained by the blood stream from the lymphatic system and accompanied by a local allergic tissue reaction. The author calls this a secondary lesion. 2 That the life of this lesion in its pure state is extremely short—a matter of a few days—and that by the end of that time its fate is determined. It either disappears, leaving a negligible scar, or else undergoes certain definite changes and certain unknown changes, becoming what may be termed an intermediate lesion. 3 That the life of the intermediate lesion is indeterminate, depending on the diathetic condition of its host, his health at the time and his environmental conditions. It either remains as an intermediate lesion, spreading by direct extension in all directions, or healing in one direction and spreading in another, or remaining dormant but unhealed, or else it heals decisively. In its healing it may either form a fibrous or a fibrocalcereous scar with no activity or may contain somewhere in its interstices small areas of an intermediate lesion. 4 That the intermediate lesion, healed as far as it may and in a nonprogressive state, is a tertiary lesion. 5 That pure tertiary lesions do not spread. Apparently pure ones if they do spread do so slowly and then only by virtue of the intermediate elements they contain. 6 That tertiary and intermediate lesions may become secondarily infected. 7 That spread of disease takes place in three ways. (a) By the appearance of a new, hematogenous, secondary lesion, which will behave in exactly the same way as its predecessor or predecessors. These new secondary lesions may occur time and time again. (b) By the spreading of an intermediate lesion by its direct extension of tissue infiltration and destruction. (c) By rapid bronchogenic spread in terminal states after hemoptysis and under anesthesia. The author concludes that, if one cannot prevent the recurrence of secondary lesions, one must admit almost a 50 per cent failure and therefore one's patients should no longer be labeled tuberculous and nontuber-

culous—and the tuberculous as active or inactive, advanced or incipient—and be herded into a sanatorium, hoping for the best when one knows that for the majority the worst will occur. The reactionary continuance of such a policy should hold one up to ridicule, it wastes public money and imposes hardships on one's patients to no useful end.

Pernicious Anemia and Hydrochloric Acid—Davidson describes a case of pernicious anemia in which the stomach regained the power of secreting hydrochloric acid and pepsin and, in all probability, the intrinsic factor of Castle. The patient has maintained excellent health and a satisfactory blood level for the past six months on a normal diet. While it is necessary to await developments for another year, it is not unreasonable to assume that this case of pernicious anemia has been cured. The patient was given two tubes daily of a fish liver extract made in Aberdeen. A reticulocyte crisis started on the third day and reached 18 per cent on the fifth day, returning to normal in twelve days. As soon as the reticulocyte crisis was well developed fish liver extract therapy was stopped. Apart from the usual hospital diet the patient received nothing further in the way of specific therapy (mammalian liver or liver extract, gastric tissue products, vitamin B preparations), drug treatment (iron or arsenic) or gastric lavage. The remarkable potency of the remedy employed for this short period is evidenced by the doubling of the blood count in twelve days and the trebling of it in twenty-one. Thirty-three days after admission, the patient left the hospital with a blood count of 4,100,000 red cells and 85 per cent hemoglobin. The liver and spleen had diminished in size, and his general health and appearance were excellent.

Injection of Pilocarpine in Treatment of Urine Retention—Katsu treated eleven patients with urine retention occurring after systematic panhysterectomy for cancer, thirteen cases of urine retention after gynecologic laparotomy, and twenty-four cases of urine retention in the puerperium, using a subcutaneous injection of from 0.5 to 1 cc. of a 1 per cent solution of pilocarpine chloride. When no results were obtained the same quantity was diluted with about 5 cc. of

physiologic solution of sodium chloride and injected into the median vein, this reduced the height of the bladder to 3 finger-breadths above the symphysis. The author concludes that the treatment can be applied in every type of urine retention. It saves frequent catheterization and prevents infection through the urinary route. When the quantity of natural urination is reduced after systematic panhysterectomy this treatment increases it markedly. It is generally effective in urine retention of other gynecologic laparotomies and during the puerperium, especially when no other treatments for the retention are effective. The by effects are slight and temporary.

Ankylosis and Posttraumatic Arthritis—A comparison of the results of sympathectomy with those of endocrine therapy in severe cases of ankylosis with pain and osteoporosis, following articular trauma or prolonged immobilization of a joint led Fischer to the utilization of acetylcholine. Its chief action is vasodilation of the small peripheral arteries. The success obtained with it in the treatment of varicose ulcers made him think that in certain cases of articular ankylosis it might have a similar action to that of sympathectomy. He first used acetylcholine in old cases of ankylosis in poorly reduced fractures and in cases of painful stiffness following immobilization. The results were so favorable that he tried this treatment as a preventive in recent fractures, by giving injections of acetylcholine during immobilization. From the results of thirteen cases which he reports, he concludes that any articular trauma or any immobilization of a limb which may cause ankylosis of the joint is amenable to treatment with acetylcholine. The treatment should be started during the first days of immobilization and prolonged according to the condition of the joint. If the joint is relatively supple at the end of immobilization, a few injections of acetylcholine will quickly cure the persistent stiffness. If a severe, painful stiffness or ankylosis is feared because of the patient's age, the severity of the lesion or imperfect reduction, or because the ankylosis resists treatment or is of long standing, the injections of acetylcholine should be given daily. The amount needed for a full treatment is from fifteen to twenty ampules of acetylcholine (Roche) in 1:10 dilution; it may be increased during the first days of immobilization if a retardation is feared. The treatments accelerate complete cure. Ankylosis disappears rapidly with this treatment and, in cases of intra-articular fracture or an immobilized joint, the joint retains its mobility when the cast is removed. In contrast with sympathectomy, this treatment does not increase osteoporosis, in some cases it does not affect it and in other cases it decreases it. The author offers the following hypothesis to explain the action of acetylcholine. There is partial vasoconstriction of the secondary arterioles in a traumatized region; acetylcholine relieves the vasoconstriction and has a favorable effect on the calcium metabolism.

Pathogenesis of Chronic Pulmonary Tuberculosis—

According to Kalbfleisch, it is generally accepted that the dissemination of tuberculosis from a primary focus after it has been at rest for a longer period is comparatively rare. A relation between an old primary focus and new tuberculous tissue products in the lung can be established as certain only on the basis of the following factors: spatial relations between the two, absence of other foci, absence of new tuberculous changes in the regional lymph nodes of the lung and absence of tuberculous changes in the organs of the systemic circulation. In all other instances the interrelation between primary complex and chronic pulmonary tuberculosis is only an assumption and in the majority of cases it will be possible to demonstrate that so called exogenous or endogenous reinfections from the early period of the primary lesion were the point of origin for the exacerbation. The author studied cadavers in order to determine whether exacerbations originating in the old primary focus could be definitely established. He describes two cases in which the occurrence of exacerbations of calcified primary foci could be demonstrated. However such an occurrence is extremely rare and is not identical with the pathogenesis of a pulmonary phthisis. On the contrary it was found that the changes of the exacerbated calcified primary focus were limited to its capsule and its immediate surroundings. There may be exceptions but the author is convinced that they are extremely rare. He stresses the fact that exacerbations of calcified primary pulmonary complexes are possible, that they are extremely rare in the pulmonary portion of the complex and somewhat more frequent in the lymph node portion but that in both cases they have only a slight tendency to dissemination and that for this reason, they are only rarely the point of origin of chronic pulmonary phthisis.

Treatment of Erysipelas—Vogel states that in addition to the local treatment of grave and average cases of erysipelas, he has employed intramuscular injections of from 20 to 100 cc (generally 25 cc.) of a polyvalent antitoxic and anti-infectious streptococcic serum. He found that this serum therapy had a favorable influence on the general manifestations of the disease, particularly the temperature which decreased rapidly. The local manifestations did not yield so readily or they even spread for a day or two after the serum was administered but the pain, erythema and tenseness of the skin were lessened, and the whole process appeared to take a more benign course.

Psoriasis as Metabolic Problem—Grütz and Bürger relate studies which indicate that the underlying cause of psoriasis is probably a disturbance of fat metabolism. They consider two possibilities: (1) that the fats, which are a physiologic requirement of the skin are eliminated through the capillary system in excessively large quantities and, on entering the epidermis, produce the psoriatic manifestations; (2) it is possible that nonphysiologic or irregularly composed lipoids are the cause. In both cases the cutaneous manifestations of psoriasis could be considered as an inflammatory reaction to the pathologic supply of lipoids. Moreover, this theory would

bring psoriasis in relation with the xanthomatoses or the lipoidoses, with which it has in common a similarity in the localization of the lesions and also the fact that it is quite often a hereditary condition. The interpretation of psoriasis as a disturbance of fat metabolism is supported by the success of the dietary treatment deficient in fat content. The authors resorted to this diet in eleven cases of psoriasis. All other therapeutic measures were discontinued when the patients were subjected to this diet. In four cases that had been refractory to other treatments the fat free diet resulted in the complete disappearance of all symptoms, in five instances considerable improvements were observed and two patients, who are still being treated, likewise show improvement. The authors present photographic proof of the efficacy of the fat deficient diet in a case of severe psoriasis. Other aspects of psoriasis that can be explained on the basis of disordered fat metabolism are that butchers and farmers, in whom a diet with excessive fat content is likely, are often subject to psoriasis, that relapses of psoriasis are especially frequent during the cold season when fat consumption is usually greater, that psoriasis is primarily a disease of the colder climates and practically unknown in the tropics, and that carefully observing physicians as well as patients have found that psoriasis shows a better healing tendency when foods such as butter and fats are avoided. Reports in the literature show the efficacy of meat free and vegetarian diets in psoriasis.

Vermiform Appendix and Appendicitis—Sperrk calls attention to the structure of the vermiform appendix, which differs from that of other portions of the intestine primarily by its abundance in lymphoid tissues. The former belief that the appendix is entirely useless has been largely abandoned in favor of the theory that it is an organ with a lymphatic function. In this respect, studies have been made on various animal species and the author has continued these studies on the development and distribution of the lymphatic tissues in the intestine of certain carnivorous animals. He thinks that the development of lymphoid tissues in the intestine is dependent on the contact with the intestinal contents and on the duration of the retention of these contents. In discussing the etiology of appendicitis he evaluates the role of the bacterial flora and the significance of the diet, particularly as to whether it is mostly vegetarian or has a high protein, especially meat, content. But he also shows that a meat diet cannot be the only pathogenic factor in appendicitis. He concludes from observations on animals that a meat diet requires considerable physical activity because a rapid intestinal passage is necessary to prevent protein putrefaction. He thinks that an oversupply of proteins combined with deficient utilization and a tendency to constipation are the main factors that predispose to appendicitis. In accordance with this he thinks that appendicitis can be prevented by a suitable diet. He does not wish to be taken for an apostle of vegetarianism but he considers a diet with a high meat content inadvisable for persons with sedentary occupations.

Complement Fixation Reaction—Ensbruner and Wendlberger decided to try the complement fixation reaction for the detection of hypersusceptibility against arspenamine (1) because repeated intracutaneous tests may produce sensitization and (2) in order to be able to detect an exciting or developing arspenamine hypersusceptibility before or in the course of an arspenamine cure without exposing the patient to the dangers of sensitization involved in cutaneous tests. They give a brief report of the tests they performed on the serums of three patients with arspenamine hypersusceptibility and on forty-three control persons. In the persons with hypersusceptibility to arspenamine a deviation of the complement is evident.

Birth in Deflexed Positions of Fetal Head—Presentation of the forehead occurs in approximately 15 per cent of deliveries. This position can be recognized during internal examination by the tendency of the large fontanel, which is in the lowest plane, to rotate toward the pubic symphysis, whereas the small fontanel can hardly be reached. The delivery in this position taxes the perineum considerably, and for this reason the author recommends prophylactic episiotomy, but he thinks operative delivery unnecessary. In exceptional cases the forceps have to be employed, the typical birth mechanism should be imitated as much as possible, but an expectant attitude is generally best. Katz further discusses presentation of the face, which occurs in from 0.36 to 0.5 per cent of deliveries. He asserts that if an expectant attitude is taken, 90 per cent of the facial presentations terminate favorably for mother and child. The mortality of children born in this position is only slightly higher than that of children born in occipital presentation and consequently it is advisable to avoid the early and unnecessary use of the forceps. If it becomes necessary to terminate the delivery, Kjelland's forceps should be used. The author considers the brow presentation the most difficult of the deflexed positions. In a slightly narrow pelvis in multiparas version may be attempted, but, if the pelvis is extremely narrow, delivery by cesarean section is advisable. However, the latest statistics indicate that in this presentation likewise an expectant attitude is best for mother and child.

Examination of Gastric Juice—Heckmann describes a test that employs a protein-peptone solution and utilizes the tolerance principle in the examination of the stomach. The solution is prepared by mixing 80 cc. of a freshly prepared solution of egg albumin with 130 cc. of distilled water, 4 Gm. of Witte's peptone being added and this solution being stained with two drops of a 2 per cent solution of methylene blue. Thus the solution contains approximately 40 per cent of egg albumin and 2 per cent of Witte's peptone. Before being introduced into the stomach it is heated to body temperature and filtered through gauze. Of the total of 210 cc. of solution, 10 cc. is kept and, together with tenth-normal hydrochloric acid and tenth normal sodium hydroxide, is used for titration of the portions withdrawn from the stomach to determine the acid and alkali binding power. The remaining 200 cc. of the solution is introduced into the stomach by means of a thin catheter, following withdrawal of the contents of the fasting stomach. The first fraction of 10 cc. of the gastric contents is withdrawn five minutes after the introduction of the protein-peptone solution, the next fraction five minutes later, and each following fraction after ten minute intervals until discoloration sets in. Later the entire remaining quantity of the secretion is withdrawn. Titration reveals how much hydrochloric acid has been secreted. The normal curves obtained with the protein-peptone solution do not differ from those obtained when caffeine is used, but the protein-peptone test is of great value in all stages of subacidity. Whereas other methods show similar curves, whether the secretion of hydrochloric acid is almost completely abolished or only slightly impaired, the protein-peptone solution permits the differentiation of the following types: (1) secretion of hydrochloric acid insufficient for neutralization of the protein-peptone solution, (2) secretion of hydrochloric acid adequate for neutralization of the protein-peptone solution but not for establishing the peptone optimum,

(3) secretion of hydrochloric acid sufficient for neutralization of the protein-peptone solution and for optimal reaction of pepsin digestion. In hyperacidity the protein-peptone test generally reveals a higher degree of acidity and it frequently detects hyperacidity where other test methods fail. In chronic stenosing ulcers with accompanying gastritis the hyperacidity usually indicated by the caffeine test does not become evident in the protein-peptone test but an insufficiency of the hydrochloric acid secretion is often detected. The new method is not meant to replace the caffeine test but is intended to supplement it.

Functional Mitral Stenoses Caused by Tumors of Left Auricle—Ludwig points out that most physicians consider diastolic murmurs always indicative of an organic cardiac lesion that is they identify it with a change in the valvular apparatus. This is largely justifiable since exceptions are comparatively rare, and it surprised him when the postmortem examination of a patient who for six months had had a systolic and a diastolic murmur at the apex of the heart revealed normal mitral valves and a small myxomatous tumor of the left auricle. This tumor had produced a functional mitral stenosis. The author reviews twenty cases from the literature, in which mitral stenosis resulted from tumor of the left auricle. He calls attention to the frequency of the concurrence of myocarditis with pseudomyxomas of the left auricle and he thinks that a local involvement of the endocardium of the left auricle in the myocarditic process may lead to thrombosis. It is possible that the conditions of mechanical pressure in the left auricle are responsible for the organization and the myxomatous transformation of the thrombus. In discussing the symptomatology of the tumors of the left auricle he points out that there is not a single reliable symptom for these tumors. The symptoms that have been described are caused partly by the accompanying myocarditis (weakness of the cardiac muscle subfebrile temperatures deficient response to digitalis) partly by the thrombosis in the heart (embolic infarcts) and partly by the impairment of the mitral valve produced by the tumor.

Influence of High Fat Content of Diet on Blood in Polycythemia—Rothmann and his associates found that, when from 100 to 200 Gm of fat was added to the diet for several days the number of erythrocytes showed a considerable decrease. They decided to utilize this action of an excess fat diet in the treatment of polycythemia. They mention one case in which it was possible to decrease the number of erythrocytes from eight million to less than five million and the hemoglobin content from 155 per cent to 122 per cent. This case reacted most favorably yet there were several other cases in which a decrease of the erythrocytes could be effected by alternating between a fat deficient diet and a diet with high fat content

but to reduce the hemoglobin it was usually necessary to resort to venesection. The authors cite reports from the literature that indicate the hemolytic action of fatty acids and cite their own observation on a dog in which the injection of 5 and 10 per cent neutralized caproic acid resulted in a considerable decrease of the erythrocytes. They pointed out that the erythrocyte reducing action of fat should be given consideration in conditions other than polycythemia. They suggest that in the period of convalescence, in the treatment of tuberculosis and in renal and hepatic diseases the fat intake should be restricted to the minimum requirements. They consider the high fat content of the diet of tuberculous patients unfounded although they realize the significance of fat as a carrier of vitamins.

Increased Arterial Pressure in Young Persons—Weinrich investigated whether blood pressure increases are present in young persons. His studies were made at an advisory station for athletes on 2,200 young men aged between 13 and 39 the majority being between 17 and 27. Only those who were entirely healthy were considered for the blood pressure studies. The results of the tests are shown in tabular reports. For the purpose of better classification the author divides the examined men into three groups: those whose blood pressure is less than 100 mm. of mercury; those in whom the pressure is between 100 and 130 mm., and those with a pressure of more than 130 mm. In the greatest majority the pressure was between 100 and 130 mm., and only in the younger boys was this middle group somewhat smaller. Beginning with the age of 17 this middle group comprised approximately 80 per cent of the examined youths. The group of those aged between 28 and 33 was an exception to this, in that the middle group amounted to 93 per cent. The percentage of youths with a pressure of less than 100 mm. decreased steadily with advancing age. In the young men between the age of 19 and 27 the incidence of this pressure amounted to about 4 per cent whereas in those aged more than 28 it was extremely rare. A pressure of more than 130 mm. was never observed in boys under 14 and only in eight of those aged 15. From here on the incidence of the higher pressures increased to reach about 15 per cent in those aged 19 and to remain approximately at this percentage up to the age of 28 but in the men between 28 and 33 there was a decided drop in this group the incidence of pressures of more than 130 mm. being only 6 per cent. The average in the group of higher pressures was 140 mm., but there were also some with 160 mm. and even with 175 mm. The author points out that pressures of more than 150 mm. are generally considered abnormal particularly in young persons but, because he found these youths to be entirely healthy, he is ready to doubt this. He thinks that the normal variations of blood pressure may reach into higher values than is generally believed. However he admits the possibility of another interpretation. He thinks that these youths with the high pressures may later develop true arterial hypertension and considers the absence of symptoms no proof against this since it is known that arterial hypertension may exist for a number of years without causing trouble. He considers it advisable to examine these youths with high pressures from time to time and to watch whether in later years they develop symptoms of hypertension.

Takata-Ara Reaction (Jezler Modification) in Diseases of Liver—Rohrer points out that the exact diagnosis of the disturbances in which enlargement of the liver, ascites and icterus exist is still difficult. However he considers Jezler's modification of the Takata-Ara reaction which was described in the *Schweizerische medizinische Wochenschrift* 60 52 (Jan 18) 1930 and abstracted in *THE JOURNAL* March 29, 1930, page 1024 a valuable aid. He employed it in tests on 125 serums from 108 patients. The results of the tests, the positive outcome of which is based on a shifting of the ratio of albumins to globulins in favor of the coarsely dispersed phase are compared with the sedimentation speed of the erythrocytes. The author made the following observations. Of eighteen patients with a positive seroreaction, fifteen had cirrhosis of the liver, one had chronic ethylism without clinically demonstrable disorders of the liver, one had carcinoma of the descending biliary passages but simultaneously existing cirrhotic processes of the liver could not be excluded and one had diabetes mellitus with fatty degeneration of the pancreas.

without cirrhotic changes of the liver. Among eighteen patients with a weak positive seroreaction there were seven with cirrhotic changes of the liver, two with chronic ethylism and without signs of a hepatic disturbance and nine with hepatic disorders but without signs of a cirrhotic process. Of the seventy-two seronegative cases twenty-three presented cirrhotic processes of the liver and ten presented chronic ethylism. In patients with ascites a positive reaction was observed only when a cirrhotic process existed in the liver. The reaction was positive in other puncture fluids (1) when the patient also had cirrhosis of the liver (puncture of the knee joint) and (2) in two pleural punctures in patients with exudative pleurisy of tuberculous etiology but without any signs of hepatic disorder. The author concludes that as an indicator of a disturbed albumin-globulin ratio the Takata-Ara reaction is superior to the erythrocyte sedimentation speed. He also thinks that in the serum and in the ascites fluid it is a great help in the differentiation of cirrhotic from other hepatic processes. Flocculation in four or five different concentrations usually favors cirrhosis of the liver but a negative reaction does not exclude cirrhosis. In the evaluation of a positive reaction in exudative pleurisy of tuberculous etiology, precaution is necessary.

Action of Baths on Circulation.—Winterstein and Fraenkel-Tessmann call attention to studies conducted by Bornstein and his associates in which the influence of baths on the minute volume of the heart of healthy persons was determined. Bornstein employed the method described by Grollman but, instead of using acetylene employed nitrous oxide and made the surprising discovery that warm baths of from 32 to 33 C (89.6 to 91.4 F) and still more those of from 38 to 39 C (100.4 to 102.2 F) increased the minute volume to twice or three times the original value, whereas cold baths effected a slight decrease in the minute volume. The beat volume changed in the same manner although not quite as severely, whereas the amplitude of the blood pressure was not noticeably changed. Bornstein tried to explain this contradiction by the hydrostatic conditions of the bath. Since Grollman's acetylene method appears to be the best for the determination of the minute volume, the authors decided to repeat the experiments of Bornstein and make the tests with acetylene instead of nitrous oxide. They found that in healthy persons warm baths either cause no change or cause a slight decrease in the minute volume of the heart.

Thyrototoxic Arrhythmias.—Parade shows that in addition to the well known tachycardia originating in the sino-auricular node, patients with exophthalmic goiter frequently show disturbances of the cardiac rhythm which are a result of the pathologically increased action of the thyroid gland. The author's report is based on observations made on 188 patients with exophthalmic goiter. He observed two types of disturbances in the cardiac rhythm: extrasystole and auricular fibrillation with absolute arrhythmia of the ventricles. The extrasystoles which may be either ventricular or auricular, are comparatively rare. The author observed five cases of ventricular and three of auricular extrasystole. The most frequent disturbance in the cardiac rhythm of patients with exophthalmic goiter, namely, auricular fibrillation with absolute arrhythmia, may be temporary or may become permanent. The author noted that the temporary fibrillation generally concurred with an exacerbation of the other symptoms of exophthalmic goiter; the excitation was more pronounced the exophthalmos became exacerbated and the sweating was more profuse. This seems to indicate that the paroxysmal fibrillation is due to an acute increase in the toxic products of the thyroid. On the other hand, it is possible that the excitability of the sympathetic nervous system suddenly increases (as the result of joy, fright or overexertion) rendering the toxic action of the thyroïdal secretion more effective. It is probable that the two factors run parallel. If the exophthalmic goiter does not improve, the accesses of auricular fibrillation may become a permanent condition with absolute arrhythmia of the ventricles. The author found that older patients with exophthalmic goiter are especially subject to absolute arrhythmia. The most important factor in the treatment of thyrototoxic arrhythmias is to prevent intoxication of the organism by the secretion of the thyroid. After this has been accomplished the cardiac disturbances disappear or remedies such as quinine

can exert their action, which is impossible as long as the thyroïdal intoxication persists. He advises resorting to iodine treatment only in the hospital where constant control is possible and as a rule, only when resection of the thyroid can be done as soon as the height of iodine action has been reached. The disturbances of the rhythm developing after the operation are, as a rule, readily counteracted by quinine. The author states that roentgenotherapy can be tried in most cases of exophthalmic goiter, but if after three months there is no improvement, surgical treatment should be instituted. Early operation usually gives the best prospects for a complete cure.

Empyema of Children.—Klages reports on ninety eight patients treated since 1926 in the surgical clinic of Voelcker. Of these, thirty were nursing infants and very young children. The mortality rate was 7 per cent. The author is impressed with the advantages of a combined method of rib resection and closed drainage. The patients were treated by aspiration until the pus became too thick to flow and were then operated on. The method consisted of a typical rib resection, always under local anesthesia, the making of a small incision into the pleura and the introduction of a long rubber tube. A finger cot was tied to the end of the tube and, after from twelve to fourteen days, open drainage was resorted to by cutting off the end of the tube. In order to avoid residual cavities, the average duration of drainage did not exceed twenty-nine days. They did not irrigate. Deformities of the spine were prevented by proper orthopedic exercises. The average duration of treatment with the method described was forty-six days.

Operative Treatment of Gastropsis.—According to Pribram operations for ptosis and especially for gastropsis have fallen undeservedly into bad repute. Perhaps it is not sufficiently appreciated that our organs are suspended by an arrangement so complicated and so skilful as to rob them of their weight. One of the basic causes of ptosis is to be seen in the disturbance of the coordination in this suspension mechanism, resulting in displacement of organs by the force of gravity. The patient becomes conscious of the weight of the organ so that every change in posture brings about painful sensations, which may range from a sense of mild pressure to severe pain. This pathologic awareness of the weight of an organ constitutes the essence of ptosis as a clinical entity. Emaciation characteristically accompanies gastropsis. Discomfort and nausea after eating lead to limitation of food intake and further favor loss of fat and progression of the general enteroptosis. The author believes that patients with a clear-cut case of gastropsis can be benefited by the operation of gastroplication. He considers gastro-enterostomy worse than valueless in this condition, and the various forms of stomach resection too formidable. In his method three or four rows of plicating silk sutures are introduced into the anterior wall of the vertical portion of the stomach. The horizontal portion consisting of the antrum and the pylorus and concerned with the emptying act is not disturbed. The sutures are brought out and are tied in the intercostal spaces. Of the twenty four patients

operated on by the author, thirteen were followed up for from three to eleven years. Eight of these were found to be in excellent condition and symptom free, and five were improved and symptom free.

Calcium Therapy of Acute Inflammations of Adnexa—Von Fekete points out that ten years ago he began to treat acute inflammations of the adnexa with injections of calcium. He mentions the following factors as involved in the action of calcium: the specific action producing a greater impermeability of the vascular endothelium; the pain-allaying action; the reduction of the susceptibility of the cells to inflammatory irritants; and the eventual increase in the acid values of the blood. He reviews a number of favorable reports in the literature since his article appeared and relates his experiences with ninety-one patients whom he treated with calcium injections from 1924 to 1931. He resorted to calcium treatment in patients with acute adnexal inflammations of not more than from two to four weeks standing. Older processes were treated with calcium when they showed signs of exacerbation or of spreading of the process, in order to overcome or reduce the symptoms of the acute process: exudation, pain and irregular hemorrhages. The calcium was administered by intravenous and by intramuscular injections. He never observed injurious effects from the injections but found that the pain disappeared within a few days. He considers the rapid checking of the inflammatory exudation the most essential action of calcium. He discusses the surgical treatment of the adnexa and shows the value of the calcium in the preoperative and in the post-operative period.

Parathyroid Hormone and Calcium in Uterine Hemorrhages—Bakács resorted to the simultaneous application of parathyroid extract and of a calcium preparation in fifty-three cases of abnormal uterine hemorrhages. In the majority of patients the hemorrhage was of hypermenorrheal nature. The injections were made into the gluteal muscle. Good results were obtained in metrorrhagia haemorrhagica and particularly in hypermenorrhea. In the latter condition the simultaneous use of the two substances gave better results than hormonal therapy alone, but mild hypercalcemic symptoms developed occasionally. The method proved of symptomatic value, and the effects were lasting in many instances. The author thinks that this is the result of functional changes in the parathyroids or in the entire excretory system.

Ultraviolet Irradiation of Circulating Blood in Septic Diseases—Since the penetrative power of ultraviolet rays through the layers of the skin is too slight to have an effect on the bacilli circulating in the blood, Frommer exposed a large vein (the vena basilica or the vena jugularis) for a length of from 15 to 18 cm. and removed the adventitia. Following the intravenous injection of 25 cc. of a 1 per cent solution of eosin, ultraviolet radiation was applied to the exposed vein for from six to seventy minutes. The author employed this treatment in six cases of severe sepsis. Three of the patients recovered. The first of these patients, who received two irradiations of six and twelve minutes, respectively, had a generalized sepsis with hemolytic streptococci which developed following an operative intervention for purulent otitis media; the second had a staphylococcal sepsis that developed following manual removal of the placenta, and the third had sepsis resulting from abortion in the third month of pregnancy. The latter two received two irradiations each of thirty and thirty-five minutes, respectively. Of the three patients who died, two

were puerperal women who had pyemia and septicopyemia and purulent, pulmonary metastases; the third woman had endocarditis lenta. Whereas, in the three women who recovered the skin around the wound soon developed an erythema, the three who died showed no erythema in spite of the fact that they were exposed to the rays for longer periods. The author thinks that this sign may eventually prove to be of prognostic significance. He realizes that the limited number of cases observed by him does not permit a final evaluation of the treatment, but he thinks that it has a regenerative effect and increases the resistance, and that, because it is without danger the method should be tried in cases of sepsis coming for treatment during the early stage.

Epidemic Meningitis Simultaneous with Measles. I. Ya. Shterman—p 355

Serum in Treatment of Measles—Dulitskiy points out that popularization of the 'crèche' idea brought about a more urgent need of safeguarding against contagions. The most important of these is measles, owing to the high mortality of the disease in the first year of life. Because of difficulty in obtaining convalescent serum for immunizing purposes, Degkwitz suggested the use of adult blood serum on the assumption that approximately 90 per cent of all adults had had measles. The author suggested in 1924 the use of placental blood obtained a few minutes after the delivery. The dose adopted, 20 cc., was not sufficient to prevent the disease but resulted in a mild course and insignificant mortality. It was of advantage to institutions to have the children pass through a mild course and acquire an active immunity instead of a temporary passive immunity conferred by the use of a sufficient amount of adult blood serum or placental blood serum. Parents bringing a child to the crèche are obliged to give blood for the preparation of the serum. The influence of immunization on the mortality was strikingly demonstrated by a reduction of the mortality in children under 1 year of age from 39.6 per cent to 4.6 per cent and in children from 1 to 3 years of age from 19.8 per cent to 2.8 per cent. No difference was noted in the effect of adult blood serum or placental blood serum. Reactions were observed very infrequently and amount to no more than a rise in temperature. The serum loses its potency after thirty days.

Epidemic Cerebrospinal Meningitis—Neits states that the incidence of epidemic cerebrospinal meningitis, a relatively rare disease twenty-five years ago, has been on the increase in the central states of the Soviet. The statistics of the pediatric clinic of the Voronezh Medical Institute show that there were 127 cases in 1927, 583 in 1930 and twice that number in 1931. The disease affects children almost exclusively, and because of high mortality and severe complications, becomes an important factor in the morbidity of childhood. Analysis of the cases did not reveal any special predisposing etiologic factors, except that of age. Experience in this respect coincided with that of the rest of the authors in that the youngest children were far more likely to be stricken. In the statistics, the incidence up to the end of the first year amounted to 49 per cent, from 1 to 2 years to 16.5 per cent, from 2 to 4 years to 19.5 per cent, from 4 to 6 years to 7 per cent and after that the incidence sharply declined to about 0.7 per cent. The greatest number occurred regularly during the early spring and the late autumn months, coinciding with the highest incidence of infections of the upper respiratory tract. To study the effect of specific treatment the author selected a group of 126 patients, who received no treatment of any kind until their admission to the clinic, and in whom the clinical diagnosis was verified by bacteriologic examinations. In a group of twenty patients treated without serum or vaccine, there were eighteen deaths. In thirteen severe cases in which vaccine alone was used, there was a mortality rate

of 50 per cent. In seventeen severe cases in which serum alone was used, the mortality amounted to 70 per cent. In forty-five severe cases in which both serum and vaccine were employed, the mortality rate was 25 per cent. The author concludes that the best results were obtained by combining the serum and autovaccine therapy. In one treatment, 10 cc of antimeningococcus serum was given by the endolumbar route and at the same time an equal amount was administered intramuscularly. An autovaccine, prepared from the fluid obtained at the first spinal puncture, was standardized to contain 5,000,000 killed microbes per cubic centimeter. The initial dose was 0.1 or 0.2 cc and was increased up to 0.5 or 0.6 cc. Injections were made on alternate days. In case of a dry puncture, the author resorted to the suboccipital route but he did not notice any advantage over the spinal method. There has not been one instance of serious shock or death from the injections. Serum reaction was noted in 32 per cent. The serum and autovaccine treatment was effective in materially diminishing the mortality. The average duration of the disease was reduced to three weeks when both vaccine and serum were used and to six weeks when vaccine alone was used. The specific treatment was most effective when applied within the first ten days but had no effect after the fourteenth day. The grave complications of blindness, deafness or chronic hydrocephalus were observed in a single instance when patients were treated with specific therapy.

Specific Serum in Diphtheria—Yarotskiy takes a stand against the single large dose of antitoxin in the treatment of diphtheria. He believes that the size of the individual dose as well as the number of injections is to be determined by the patient's condition. He administers 10,000 units to begin with and, in severe cases, repeats the dose the same day. The essential feature of his treatment consists in daily intramuscular injections of antitoxin until all signs and symptoms have disappeared. Injections are kept up until the patient presents the appearance of normal health. Edema of the uvula, hyperemia of the throat, excoriations of the epithelium and swollen tonsils demand further injections. Anemic or apathetic appearance suggests persistence of intoxication and calls for further injections. The author considers it fallacious to treat cardiac involvement by stimulants alone. When examination reveals beginning dilatation of the heart chambers, murmurs, muffled sounds, accentuation of the second pulmonic sound, tachycardia or bradycardia, an additional dose of antitoxin will avert collapse and a fatal outcome. The author recommends an additional dose for severe cases from four to five days after the disappearance of all signs and symptoms. The daily dose in laryngeal diphtheria was 10,000 units. The author had 9 fatalities in 377 cases, a mortality rate of 2.4 per cent. In seven of these his method was not adhered to. When these are excluded, the mortality in the group is 0.5 per cent. The author sees in deviation from his method the main cause of mortality in diphtheria.

Hormonal Sterilization of Female Organism—Mandelshtamm and Chaykovskiy proved in a previous study that injections of prolan B in animals cause a temporary sterility. The resulting formation of corpora lutea arrests follicular growth, creating a state of pseudopregnancy. The authors made observations in ten women with normal menstrual cycle about to be operated on for some such condition as uterine fibroma, cancer of the cervix or cyst of one ovary. Freshly prepared prolan was administered in doses of from 100 to 200

mouse units until, in the course of a few days, the patients received from 400 to 1,100 mouse units. They were operated on from two to twenty-six days after the last injection. Serial histologic sections of ovarian tissue removed at operation demonstrated in each case defective ova in the maturing and matured follicles, disintegration and disappearance of the membrana granulosa, cystic dilatation of the follicles, development of numerous corpora lutea, and hyperemia and hemorrhages into the follicular tissue. The degenerative changes produced render the follicles insusceptible of being fertilized. The authors conclude that (1) various doses of prolan are well borne by women, (2) administration in the course of a few days of from 400 to 1,100 mouse units of prolan results in profound degenerative changes in the follicular apparatus, (3) the histologic changes produced suggest that the foregoing doses are sufficient to cause sterility. They question the harmlessness of temporary hormonal sterilization for the general health of the organism as well as for future generations. The absence of degenerative changes in the ovaries of pregnant women is to be explained by the protecting antagonistic action of other hormones present.

Norsk Magasin for Lægevidenskapen, Oslo

No 241 360 (March) 1933

- *Tuberculous Primary Infection and Tuberculous Disease. H. J. Ustvedt.—p 307

Aneurysms at Base of Brain—Harbitz states that aneurysms at the base of the brain are not rare and frequently cause subarachnoidal and intermeningeal hemorrhages, often fatal. In the last twenty years he has seen eighteen such cases, mostly ascribed to arteriosclerosis. Symptoms are often present for days or weeks before sudden rupture and death. Aneurysms at the base of the brain may also be the result of trauma. Congenital anomalies may play a part. Acute alcoholic intoxication is a disposing factor. In younger persons arteriosclerosis can usually be disregarded. From the literature the author cites cases of aneurysms of the brain assumed to be of traumatic origin, but he finds fairly certain cases lacking. In his personal case of a man aged 31 who had been perfectly well until he sustained a considerable trauma of the head in April 1927, symptoms of brain disturbance set in immediately after the accident and continued till January 1932, when death occurred. In his opinion the history of the case and the necropsy results connect the aneurysm with the trauma. The possibility of a slight latent aneurysm at the time of injury cannot be excluded, but in such cases the trauma of the head must have been an essential cause for the development of the aneurysm.

Gonorrheal Complications—Thygitta and Waaler used the complement fixation test in 130 serums, 95 from cases of gonorrhea with and without complications and the remaining 35 from different disorders of the urogenital tract or arthritis. The reaction was positive in 81 per cent of all certain gonorrhea cases, and in 96 per cent if the pure acute anterior gonorrhea cases are included, in which only four of nineteen tests were positive. The dried gonococcus antigen used in the tests showed no increase in spontaneous inhibition of hemolysis or change in fixation power after the lapse of one year. A simple technic with the use of human complement, such as the Noguchi Wassermann technic, excelled the ordinary technic in borderline cases. The authors consider the reaction of undoubted value for the clinician in deciding the etiology of obscure disturbances of the urinary tract, but useful for the determination of the time of recovery from a gonorrheal disease only with the most critical application.

Tuberculous Primary Infection and Tuberculous Disease—Ustvedt's investigations indicate that the first tuberculous manifestation during school age as well as in infancy and during earlier adult age follows fairly closely after the primary infection.

COMPENSATED CIRRHOSIS OF THE LIVER

A PLEA FOR MORE INTENSIVE CONSIDERATION OF THE
EARLIER STAGES OF DISEASE OF THE
HEPATIC PARENCHYMA

CHARLES B. CHAPMAN, M.D.
WELCH, W. VA.

ALBERT M. SNELL, M.D.
ROCHESTER, MINN.

AND
LEONARD G. ROWNTREE, M.D.
PHILADELPHIA

In a former paper we¹ expressed the opinion that the institution of treatment of cirrhosis of the liver both medical and surgical, is too long delayed and that in most cases diagnosis is not made until decompensation of the portal circulation is apparent, at which time the prospect of ultimate cure is remote or absent. The development of ascites and edema is of ominous prognostic significance, as Aretaeus² remarked of dropsy, "very few escape from it, and they more by fortune and the gods than by art." Successful treatment demands earlier recognition and earlier attempts at treatment.

It has been observed that cirrhosis is often overlooked clinically and that it is first recognized at necropsy almost as often as it is correctly diagnosed during life. It is also well known that in the human subject and in the experimental animal extensive hepatic injury may be present without definite signs or symptoms. It is obvious that earlier recognition of these latent cases should make it possible to protect patients from further injury from hepatotoxic substances, even if active therapeutic measures cannot always be applied. This paper is based on the clinical study of a group of cases presenting the earlier symptoms of diffuse hepatic disease, earlier diagnosis, prognosis, protection and treatment are considered.

The term cirrhosis is used here in its broad sense and refers to any type of diffuse chronic degenerative or inflammatory lesion of the liver in which the structure is grossly injured or disorganized. We believe that the so-called atrophic cirrhosis with ascites (decompensated cirrhosis) represents a common end-stage of such processes and that it is not necessarily a specific pathologic

entity. We believe also that diffuse hepatic disease of almost any type may progress to cause portal obstruction, portal hypertension, and ascites. Thus, we shall consider all types of chronic hepatic disease which may, if unrecognized and uncontrolled, progress to the decompensated or ascitic stage. Such inclusion precludes any sharp pathologic differentiation of individual groups. We have, therefore, grouped our cases on the purely clinical basis of etiologic factors, whenever these were known.

There were fifty-eight cases in our series. Forty of the patients were men and eighteen were women, all but sixteen were more than 40 years of age. The youngest patient was 20 and the oldest 80. In twenty-one cases, surgical confirmation of the diagnosis was possible. In the remainder, diagnosis was based on the finding of hepatic enlargement with or without jaundice, and on the results of tests of hepatic function. In many cases a history of some etiologic factor aided in establishing the diagnosis, and in others associated splenic enlargement and other signs of combined hepatosplenic disease were aids. In each case care was taken to rule out malignant or parasitic disease, amyloidosis, or other causes of hepatic enlargement. Although the degree of accuracy in cases in which the diagnosis was not confirmed surgically is somewhat doubtful, nevertheless there was no reasonable doubt concerning the existence of disease of the hepatic parenchyma. The cases included biliary cirrhosis, hepatitis of possible syphilitic origin (excluding simple circumscribed gumma), alcoholic cirrhosis, residual cirrhosis from previous obstructive lesions of the biliary tract, and splenic anemia with cirrhosis. Cirrhosis secondary to hemolytic icterus was not included.

ETIOLOGY

Twenty-five of the fifty-eight patients had used alcohol freely or even excessively, ten gave a history of syphilis, or they manifested some physical or serologic signs of its presence, five had suffered previously from hyperthyroidism, and fourteen had either a history or present evidence of cholecystic disease. Typhoid and malaria were each mentioned by nine patients. Six patients had the definite syndrome of splenic anemia. In twenty-three of the fifty-eight cases, more than one possible etiologic factor was present. In ten cases there was neither history of previous disease which might have affected the liver, nor objective evidence of any hepatotoxic factor, either past or present.

The large number of cases in which there was an alcoholic history is noteworthy. The incidence of probable syphilis (17.2 per cent) is considerably higher than that prevailing in the general population, but this fact is of little significance in such a small series of cases. Typhoid and malaria were of doubtful etiologic significance in this group. The incidence of cholecystic dis-

2. Aretaeus. *The Extant Works*. London, New Sydenham Society, 1856, vol. 20.

case was high. Whether the disease as is noted in these cases was primary or secondary is of course not known, obviously this may vary in individual cases. In the presence of biliary cirrhosis secondary to stone in the common bile duct, a previous infection, or inflammatory disease of the biliary tract, the lesion in the gallbladder may be regarded as undoubtedly primary. The incidence of disease of the gallbladder associated with cirrhosis is high, but the incidence of advanced cirrhosis in disease of the gallbladder is relatively low and often overlooked. That cholecystitis is sometimes merely part of or secondary to the cirrhosis should be more widely recognized. Recent observations by Judd, Nickel and Wellbrock³ on hepatitis and cholecystitis confirm previous observations on the close association of the two disorders.

Five of the patients had previously suffered from hyperthyroidism. The relation of this condition to hepatic injury was first called to our attention by McIndoe,⁴ and the recent studies of Beaver and Pemberton⁵ clearly demonstrate the possibilities of residual injury to the liver even after successful thyroidectomy. The liver as well as the heart suffers in hyperthyroidism, whether from overwork, toxemia or both is not clear.

The intimate relation of the spleen to hepatic disease is emphasized by the six cases in our series of Banti's disease with secondary cirrhosis as well as by four cases of so-called secondary splenomegaly with cirrhosis. Although such distinctions with regard to hepatosplenic disease are probably artificial, it is generally held that primary splenic anemia with secondary hepatic changes pursues a more favorable course, particularly after splenectomy, than if the hepatic lesion is the primary factor.

In two cases the onset of hepatic disease was associated with acute infection of the upper part of the respiratory tract, and in one case with an infectious process, probably streptococcal. Such cases emphasize the relation of infectious processes in the causation of hepatitis which may go on to cirrhosis. Jones and Minot⁶ have reported cases of infectious jaundice which progressed to actual cirrhosis. Recently Moon,⁷ and MacMahon and Mallory⁸ reviewed this subject and presented cases of hepatitis and cirrhosis probably due to streptococcal infection. The significance of infection as the cause of recurring jaundice and of acute exacerbations of hepatitis and cirrhosis is widely recognized.

Although single factors may cause cirrhosis, a multiplicity of chemical and infectious agents acting simultaneously or in sequence are probably the usual causes of degeneration and fibrosis of the liver. Opie's⁹ work on the combined effect of bacteria and chloroform, Bollman and Mann's¹⁰ experiments with the administration of combined alcohol and carbon tetrachloride, and the twenty-three cases of our series in which possible etiologic factors were multiple, illustrate this point.

SIGNS AND SYMPTOMS

The complaints noted on the patients' admission to the Mayo Clinic were loss of weight in twenty-one cases, asthenia in thirty-eight, flatulence in thirty-three, abdominal pain in thirty-three, jaundice in thirty-one, constipation in seventeen, diarrhea in eight and gastrointestinal hemorrhage in sixteen. In two cases only there were no symptoms which could be ascribed to hepatic disease at the time of examination. In other words, in fifty-six of the fifty-eight cases, the cirrhosis cannot be strictly regarded as latent. It would appear that careful examination in so-called latent cases may elicit symptoms or signs at some time in the course of the disease. The history, also, may suggest data of importance. In some of our cases the symptoms and signs have been present for years. Symptoms at the time of examination had varied from a few months to twenty years, the average duration was from three to five years. In one case the duration of symptoms was not known, and in two cases an enlarged liver had been noticed ten and fifteen years, respectively, before our examination. The primary symptoms mentioned in forty-eight of the fifty-six cases may be tabulated as follows: indefinite indigestion, usually associated with flatulence, in sixteen cases, pain, colic or soreness in the region of the liver in fourteen cases, severe constipation in three cases, jaundice in six cases, gastrointestinal hemorrhage in five cases, diarrhea in two cases, and enlarged liver in two cases. On the basis of the complete history, which included all complaints up to the time of the patient's admission, the fifty-eight cases are grouped according to the major symptoms: gastro-intestinal symptoms with hemorrhage in eleven cases, gastro-intestinal symptoms with jaundice in twenty-four cases, gastro-intestinal symptoms with both hemorrhage and jaundice in three cases, hemorrhage only in two cases, jaundice only in four cases, and various gastro-intestinal symptoms only in fourteen cases. In none of the cases was there a history of ascites, but in about a third of the cases a history of slight edema of the ankles could be elicited on questioning. It may be noted that jaundice and hemorrhage were frequently mentioned, in many cases, recurrent transient jaundice had been noted over long periods of time. It is impossible to relate these episodes of jaundice to any known factors in the history, but presumably they represent periods of progressive hepatic degeneration. There appeared to be no constant relationship between these episodes and those of gastro-intestinal hemorrhage, although we have observed such relationship in decompensated cirrhosis.

Although asthenia and loss of weight are fairly common in such cases, many of our patients were obese. Prostration and marked loss of weight were rare. The average loss of weight was 23½ pounds. Three patients lost 67, 65 and 60 pounds (30.4, 29.5 and 27 Kg.), respectively, one patient lost 39 and one 35 pounds (17.7 and 16 Kg.), and the remainder lost amounts below these figures.

A palpable enlarged liver was noted in forty-eight cases, a palpable spleen in twenty-seven, slight edema of the lower extremities in twenty, visible jaundice in seventeen, hemorrhoids in nine, visible collateral circulation in seven and hernia in six. Hepatic enlargement was, of course, the principal finding in most of the cases, in fact, it is doubtful whether a clinical diagnosis of compensated cirrhosis is often made in its absence. In five of the ten cases in which the liver was not found to be enlarged at the time of examination, the diagnosis

of cirrhosis was made at operation, in one case a positive test of hepatic function with bromsulphalein was thought to establish the diagnosis. The remaining four cases were classic examples of Banti's syndrome (splenic anemia), and atrophic cirrhotic livers were noted when splenectomy was performed.

Since enlargement of the liver and spleen are of so much importance in diagnosis, it seems desirable to record all our available data on this point. In the twenty-one cases in which a surgical diagnosis of compensated cirrhosis was made, the size of the liver apparently varied considerably, in eleven cases the liver was described as atrophic and in nine as hypertrophic. In the remaining case, unilateral and almost complete atrophy of the left lobe was noted, the right lobe was also markedly contracted. Notes on the size and weight of the spleen were available in twelve cases, and the sizes varied from twice normal to one spleen weighing 1,270 Gm. The clinician's estimate of the size of the liver and spleen was relatively accurate and corresponded with the surgeon's estimate. These figures give evidence that the presence of an enlarged liver or spleen may be taken at its face value, at least in cases of latent or compensated cirrhosis of this type.

Other physical conditions are less significant. The presence of visible jaundice in seventeen cases is not remarkable in view of the fact that antecedent attacks had occurred in many of the cases. We have commented on the significance of hernia as an early symptom of decompensated cirrhosis and as a common symptom in the well advanced stage of ascites. An explanation of the presence of edema in the lower extremities involves the question of the relation of the liver to metabolism of water. Partial hepatectomy, for example, may occasionally produce generalized edema. Clinical data on this point are lacking, but Addison¹¹ once said in discussing peripheral edema of patients with fatty livers: "I think it is not improbable, therefore, that this degeneration of the liver may, like mottled kidney, occasionally prove a cause of anasarca." Von Frerichs¹² stated his belief that the edema is due to the backflow through collateral vessels, resulting in increased pressure in the circulation of the lower limbs. Although the mechanism of edema in such disease of the liver is obscure, it has been widely noted as a forerunner of ascites and for this reason should be regarded as significant. It may therefore be assumed that, in cirrhosis of the liver, edema of the feet with the appearance of collateral circulation indicates danger of impending ascites.

LABORATORY DATA

Laboratory data in the group as a whole were remarkable chiefly for changes in blood count and test of hepatic function as shown by bromsulphalein.

Moderate secondary anemia with erythrocytes varying from 3,000,000 to 4,000,000 was noted in about a third of the cases. More extreme degrees of anemia could usually be correlated with a history of gastrointestinal hemorrhage. No explanation for this was apparent in cases mentioned previously. King,¹³ however, had remarked on the common occurrence of anemia during the ascitic stage. The results of bromsulphalein tests of hepatic function in this group are of considerable significance, from both the diagnostic

and the prognostic standpoints, these tests, together with the finding of hepatic and splenic enlargement, constitute our principal means of identifying compensated cirrhosis. Unfortunately, these tests are not available in every case. Retention of dye graded 1 was noted in five cases, graded 2 in five, graded 3 in twelve, and graded 4 in six. In all the cases graded 4 varying slight degrees of icterus were present, as shown by determination of the serum bilirubin (1.6 to 6 mg. for each 100 cc. of serum), and consequently the tests cannot be regarded as giving an absolute indication of the degree of hepatic injury. In twelve cases, results of the test were negative and dye was not retained in significant amounts. The results of the dye tests could not be satisfactorily correlated with the size of the liver or with the general condition of the patient at the time of the test, but its prognostic significance was considerable, as will be shown.

CLASSIFICATION

It is obviously impossible to classify accurately such a heterogeneous group of cases on a pathologic basis without data obtained from necropsy studies. It has also been emphasized that multiple etiologic factors probably were almost the rule in this group, a fact which alone prevents a sharp differentiation of cases on an etiologic basis. Although any classification is thus rendered more or less arbitrary, certain groups of cases have sufficient characteristics in common to merit special consideration. Cases probably of alcoholic origin are particularly conspicuous. It has been noted that about 40 per cent of the patients in this series of cases admitted the free use of alcohol. This is about the usual proportion of patients addicted to the use of alcohol which has been reported in other series of cases of decompensated or ascitic cirrhosis.¹⁴ Fiessinger,¹⁵ in a recent survey of the problem of cirrhosis, noted that alcoholism is held responsible in from 40 to 60 per cent of all cases of portal cirrhosis recently reported from Europe and North America. The two cases reported here are representative of other cases in this "alcoholic" group. In the first case, abstinence from alcohol has apparently served to protect the patient from progressive hepatic injury. In the second case, the lesion was far advanced when discovered, and little improvement could have been expected from any therapeutic measure, however, this patient survived three years after exploration and was in fairly good health at least part of this time, no doubt abstinence from alcohol prolonged life.

REPORT OF CASES

CASE 1—A man, aged 53, who registered at the clinic in April, 1925, had been a heavy drinker until 1924 when he had a gastro-intestinal hemorrhage of considerable severity. After convalescence from this he had no serious complaints, although his general health had been below normal. Examination disclosed that the liver was considerably enlarged and firm, and could be felt about 4 cm. below the right costal margin. The Wassermann reaction of the blood and the bromsulphalein test of hepatic function were negative, the basal metabolic rate and the blood count were normal. A test meal showed moderate hyperacidity, but roentgenograms of the stomach gave negative results. An electrocardiogram also gave negative results. Five years later the patient reported that he was well. So far as we know he has had no further trouble.

CASE 2—A man, aged 48, who registered at the clinic in March, 1927, had used alcohol freely prior to 1912, at which

time he had had a severe gastro-intestinal hemorrhage following a drinking bout. After this he did not use alcohol and remained in good health until 1920, when he began to have epigastric discomfort about an hour after meals and frequently was awakened by it at night. For three months before registration he had suffered from flatulent indigestion and had also noticed edema of the ankles. He stated that his abdomen seemed to be increasing in size. On examination he seemed to be in good general condition, although he was somewhat overweight. The blood pressure in millimeters of mercury was 166 systolic and 80 diastolic, and the ankles were slightly edematous. Neither the liver nor the spleen could be felt. Laboratory examinations were essentially negative, except for slight secondary anemia, the concentration of hemoglobin (Dare) was 65 per cent and the erythrocytes numbered 3,700,000 in each cubic millimeter of blood. A cholecystogram disclosed the presence of stones. In roentgenograms of the stomach, duodenal ulcer and evidence of pyloric obstruction were noted. Analysis of the gastric content gave evidence of free hydrochloric acid of 24 and total acidity of 46 (titrated against tenth-normal sodium hydroxide). Because of the symptoms of ulcer, the history of bleeding, and the roentgenologic signs of duodenal ulcer, an exploratory operation was advised, although a consultant had felt that the patient probably had portal cirrhosis.

The liver was found to be about half normal size, markedly cirrhotic, and with the characteristic hobnail surface. The surgeon noted the presence of cholecystitis and of duodenal ulcer but felt that any further surgical procedures were inadvisable in view of the condition of the liver. The bromsulphalein test of hepatic function following exploration showed retention of dye, graded 2. The patient returned to his home and lived fairly comfortably for three years. The cause of death was given as alcoholic cirrhosis.

Follow-up studies in cases of the alcoholic group disclosed that the mortality was higher and the duration of life after examination at the clinic shorter than in the group as a whole. Approximately half of the patients were dead on an average of two years after examination. This may mean that, by the time alcoholic cirrhosis is far enough advanced to be detected by present diagnostic means, the degenerative process in the liver has progressed to a point at which tissue cannot be restored to normal. On the other hand, there are numerous records to prove that abstinence from alcohol has resulted in restoration of health of patients with both latent and ascitic cirrhosis. Two of this series of cases followed such a course. The therapeutic implications are clear, the habitual user of alcohol who has an enlarged liver and a positive test of hepatic function with bromsulphalein is in grave danger, and he must in the future avoid all hepatotoxic substances. In view of the unusual conditions concerning consumption of alcohol in the United States in recent years, it is interesting to note that for some years prior to the World War the mortality rate from cirrhosis of the liver was from 12 to 14 per hundred thousand of the population, whereas, since 1929 it has not attained $7\frac{1}{2}$ per hundred thousand.

Other cases which merit special consideration are those associated with intermittent or chronic non-obstructive jaundice, which may be regarded as due to progressive chronic hepatitis. In the more advanced form, such cases may be designated as biliary cirrhosis. Case 2 represents a typical example of this type of case, the similarity to that vague clinical entity, Hanot's cirrhosis, may be noted.

CASE 3—A man, aged 38, who registered at the clinic in August, 1928, had been in reasonably good health, except for an attack of rheumatic fever until March, 1927, when jaundice developed following acute infection of the upper part of the respiratory tract. At this time his physician at home had noted enlargement of the liver. Since this illness he had had jaundice

intermittently to the time of his registration. He had lost 25 pounds (11.3 Kg.) and had had numerous attacks of digestive discomfort terminating in vomiting.

The patient was slightly jaundiced. The liver was considerably enlarged, but the spleen was barely palpable. The blood was normal, except for slight secondary anemia, and leukocytes numbered from 12,000 to 18,000 in each cubic millimeter of blood. The concentration of bilirubin was 4.1 mg. for each 100 cc. of serum and gave a direct reaction. Roentgenograms of the thorax and stomach gave negative results. A diagnosis was made of an infectious type of biliary cirrhosis.

The patient was examined again in June, 1930, the observations on examination were substantially the same as before. The concentration of bilirubin was 7 mg. in each 100 cc. of serum. He was seen again in 1930, at which time he had no complaints, except for some pain in the region of the liver. The abdomen had increased in size slightly, but there did not seem to be any definite collection of fluid. The liver was somewhat smaller. He had gained a few pounds and felt reasonably well. When last seen, in August, 1931, his condition was such that one might expect the development of ascites within a relatively short time.

These cases represent an unsolved problem. The etiology is unknown, and the therapeutic measures now at our command are not successful except in the occasional case. One patient formerly under our care improved temporarily by the use of emetine. Antisyphilitic treatment, given empirically, has been of little benefit. Surgical treatment has likewise been unsuccessful as a rule, although some good results have been reported following drainage of the common bile duct with a T tube. In two cases of the series, splenectomy was performed with some temporary general benefit, but without effect on the icterus or on the size of the liver. As in cases in which patients are addicted to the use of alcohol, the prognosis in the cases with icterus is unfavorable when compared to the group as a whole, of the patients presenting the picture of progressive chronic hepatitis, six died on an average of three years after examination. In fact, the course, on the average, has been distinctly unfavorable among the whole group of patients who had jaundice on admission. This is perhaps to be expected, since the development of jaundice in cases of hypertrophic or atrophic cirrhosis has long been regarded as of unfavorable prognostic significance, in fact, this observation forms the basis of one of the aphorisms of Hippocrates.¹⁶ It should be emphasized that these statements in regard to the prognostic significance of jaundice do not apply to lesions of the hepatic parenchyma which follow previous obstruction of the common bile duct from stone or stricture, although these conditions are often associated with extensive hepatitis and so-called obstructive cirrhosis or cirrhose résiduelle.¹⁷ Three patients with advanced cirrhosis secondary to biliary obstruction are included in this study, and in general they have made unexpectedly good recoveries following relief of the obstruction.

In any series of cases of cirrhosis, clinical examples of the disease may be encountered in which an etiologic factor is not apparent. In some cases the question of residual hepatic lesions from previous infectious disease has been considered as a possible causative factor, however, in reality the cause is unknown, as in the following case.

CASE 4—A man, aged 59, who registered at the clinic in October, 1925, had a definite attack of jaundice in 1900 which had lasted two weeks. He had not used alcohol and had had

16 Hippocrates. Genuine Works of Hippocrates. London: New Sydenham Society, 2: 759, 1849.

17 Fliessinger, Noel, and Albot, Guy. La cirrhose résiduelle à la suite des sténoses prolongées de cholédoque. Bull. et. mém. Soc. méd. d. hop. de Paris, 47: 150-157 (Feb. 2) 1931.

no severe infectious diseases. Since 1920 he had suffered from flatulent indigestion and occasionally regurgitated food after a full meal. He had lost 15 pounds (6.8 Kg.) in the preceding year and complained of marked weakness. On examination he was in fairly good condition. The blood pressure in millimeters of mercury was 140 systolic and 92 diastolic. The liver was greatly enlarged and extended almost to the umbilicus. Urinalysis, blood count, Wassermann reaction of the blood, and examination of the stools for blood and parasites gave negative results. Roentgenograms of the thorax, stomach, gallbladder and colon were negative. The test meal showed absence of free hydrochloric acid. Tests of hepatic function showed retention of dye graded 1. Since no source for metastatic malignancy could be made out, a tentative diagnosis of cirrhosis was made. In December, 1930, the patient reported that he was getting along quite well, except for some pain and soreness over the liver and some belching and distress after meals. Jaundice, edema or ascites had not developed and he was apparently able to carry on his usual duties.

The inclusion of syphilis as an etiologic factor in cirrhosis is open to criticism. As Fiessinger stated, it is difficult to evaluate the syphilitic factor in hepatic disease of this type. The matter has been considered fully in a paper by O'Leary, Greene and Rowntree.¹⁸ We have not included in this series any frank or proved case of gummatous syphilitic hepatitis or cirrhosis, noticing only those in which there was either a history of syphilis or positive serologic evidence of its presence together with signs of diffuse injury to the hepatic parenchyma. The inclusion of this small group has been further complicated by a history of alcoholism in several of the cases. Suffice it to say that the prognosis in this group of somewhat uncertain etiology has been surprisingly good, better on the average than that of patients with a history of alcoholism or of chronic hepatitis and jaundice. Only one of the ten patients in this group is known to have died, the other nine patients are in reasonably good health. The relative role of alcoholism and syphilis is baffling to the physician and in some cases equally baffling to the pathologist. For example, it is not uncommon to find a typical atrophic hobnailed liver at necropsy in a case previously diagnosed syphilitic hepatitis.

Six patients in the series presented Banti's syndrome of splenic anemia. Splenectomy was performed on all of these and in each instance the surgeon noted varying degrees of cirrhosis. It is of interest that five of these six patients had had hematemesis before admission. Five of the patients are still living and in reasonably good health, one patient died of unknown causes, probably hemorrhage, almost three years after operation. Splenectomy offers the greatest aid in cases of splenic anemia which have not progressed to the stage of decompensated cirrhosis with ascites, and these figures furnish further argument for early operation in such cases.

RESULTS OF OPERATION

The operative results in the group of fifty-eight cases with latent cirrhosis are of interest. For various reasons, laparotomy was performed on twenty-eight patients, twenty-four at the clinic and four elsewhere. Some of the group of twenty-four were operated on more than once, either at the clinic or elsewhere. Eleven of the twenty-eight patients are known to be dead. All except three lived longer than seventeen months after operation, these lived one, two and six months, respectively, thus illustrating the relatively

small surgical risk in this stage of cirrhosis as contrasted to the relatively high risk once ascites has developed. Talma-Morison operations were not done, although the liver was described as cirrhotic or atrophic, and there was evidence of portal obstruction in certain cases. Splenectomy was performed in twelve cases, including the six cases of splenic anemia mentioned. Eight of these patients who underwent splenectomy were living on an average of four years after operation, four died within an average of slightly less than two years. Various operations on the biliary tract (cholecystectomy, cholecystostomy and choledochostomy) were performed on ten patients, five of whom died on an average of six years after operation, the remaining five were living an average of four years after operation. The remaining six operations were explorations. Four of the patients were alive an average of thirty months after operation, and two died an average of twenty months after exploration.

These figures demonstrate that surgical exploration or even major surgical procedures do not involve a particularly high immediate risk in latent or compensated cirrhosis, and in doubtful cases exploration may be done if surgical indications exist, without fear of a high mortality because of the hepatic lesion. This is, of course, in decided contrast to the generally appreciated danger of surgical intervention after ascites has developed in portal cirrhosis.

COURSE AND PROGNOSIS

Our attempts to follow the clinical course in this group of cases of compensated cirrhosis were reasonably successful, even though details were lacking in many of the cases in which the termination was fatal. Of the fifty-eight patients in the series, twenty-five are dead. Three patients died following profuse gastrointestinal hemorrhage, two died in coma, probably of hepatic origin and one patient died as a result of intercurrent infection. Four patients died from causes not related to the liver or biliary tract. In sixteen cases there is no accurate information in regard to the terminal illness. Five patients had ascites before death, and two patients had progressive enlargement of the liver. The average duration of life dating from the onset of symptoms was about five years.

Of the thirty-three patients living, twenty reported that they were reasonably well. Six had had episodes of jaundice since examination at the clinic, and three had had gastro-intestinal hemorrhages. The remaining thirteen patients complained of gastro-intestinal symptoms of various degrees of severity. The average duration of symptoms from the onset, of the thirty-three living patients, was slightly less than eight years, this is illustrative of the remarkable latency of hepatic disease.

The duration and prognosis of the compensated type of cirrhosis as compared to the decompensated type with ascites may be summarized as follows. In the series of 112 cases of decompensated or ascitic cirrhosis reported previously,¹ eighty-four patients (75 per cent) had died on an average of sixteen months after ascites was first noted, and twenty-eight (25 per cent) are living an average of thirty-eight months after the development of ascites. In the series of fifty-eight cases of compensated or nonascitic cirrhosis, reported here, twenty-five patients (43 per cent) had died on an average of sixty months after symptoms were first noted, whereas thirty-three (57 per cent) are living an average of almost eight years after the onset of symptoms. In

18 O'Leary P. A., Greene, C. H. and Rowntree L. G. Diseases of the Liver. VIII. The Various Types of Syphilis of the Liver with Reference to Tests for Hepatic Function. Arch. Int. Med. 44: 155 193 (Aug.) 1929.

a careful study of the data in these fifty-eight cases it was difficult to elicit any one sign or symptom on which to make a prognosis in the individual case. The influence of age and sex on prognosis appears to be negligible except that in male patients who have died the duration of symptoms was much longer than in female patients. There is some evidence to show that the patients with the largest livers pursue a more unfavorable course than those whose livers were described as small. This is in contrast to the usual statement that the large liver represents an early stage of cirrhosis. It was Hanot's¹⁹ belief that variations in the size of the liver are due to differences in the type of cirrhosis and that patients with hepatic and splenic enlargement and chronic jaundice represent a slowly progressive type of hepatic disease. Price²⁰ held the opposite view, that the hypertrophic liver represents a more acute type of hepatic degenerative change. Murchison²¹ stated that the liver is not always smaller in the later stages of cirrhosis, a view with which clinicians are generally agreed. In Bollman and Mann's experiments the size of the liver seemed to be dependent on the relative amount of atrophy and hypertrophy in the same liver rather than an expression of the stage of the disease. Fagge's²² statistics seem to show that latent cirrhotic livers are larger and that the size of the liver cannot be related to prognosis. Rolleston and McNee²³ stated their belief that cirrhotic livers are large in the early

Results of Tests of Hepatic Function

	Patients Tested	Retention of Dye				
		Grade 0	Grade 1	Grade 2	Grade 3	Grade 4
Decompensated cirrhosis 112 cases 28 patients living Patients still living	87	40%	75%	20%	41%	8 7%
Compensated cirrhosis 55 cases 33 patients living Patients still living	40	75%	50%	40%	33%	33 8%

stage and decrease in size later. This observation was made also by Bright,²⁴ von Frerichs, Duckworth,²⁵ Cornil,²⁶ and Snell,²⁷ who show that, in the late stages of the cirrhosis, the liver, as seen at necropsy, is reduced in size.

Laboratory data furnish two points of prognostic interest. In this series the patients with anemia apparently had a less favorable outcome than those with normal blood. The three most anemic patients, all of whom had less than 3,000,000 erythrocytes in each cubic millimeter of blood, have died. They presented unmistakable evidence of hepatic disease. Tests of hepatic function with bromsulphalein, however, are of much more definite prognostic significance. In fact, as shown in the table, the results in this group roughly parallel those previously reported by us in decompensated cirrhosis. Seventy-five per cent of patients with

compensated cirrhosis who did not retain dye are living. In this connection it must be recalled that a negative test of hepatic function does not mean that a patient does not have cirrhosis or that the disease will not progress rapidly as it did in three of our cases in which tests of hepatic function were negative. In the ten cases in which retention of dye on tests of hepatic function was graded 1 or 2, four patients have died, one from profuse gastro-intestinal hemorrhage. In two thirds of the cases in which retention of dye was graded 3 or 4, the patients have died, most of them within a relatively short period after being examined. Although some of the patients with higher degrees of retention of dye had demonstrable jaundice and their tests cannot therefore be taken at face value, it is apparent that a high degree of retention indicates an unfavorable prognosis.

COMMENT

The cases considered in this paper represent a mixed and somewhat confusing picture. We feel that the presentation of the group is nevertheless justifiable, since so little is known about the nature, course and outcome of cases seen in the earlier phases of disease of the hepatic parenchyma. Both the lesions and the clinical pictures which they produce are largely unclassified, and indeed at times hardly lend themselves to accurate classification. The data presented seem to justify certain conclusions. It is apparent that the alcoholic patient with an enlarged liver and a positive bromsulphalein test has only about an even chance of surviving for three years or more, regardless of the fact that he has not reached the stage at which most clinicians would make an unqualified diagnosis of cirrhosis. It also appears that the patient with chronic or intermittent jaundice and an enlarged liver has an equally unfavorable prognosis. If syphilis is included as an etiologic factor, the gravity of the situation may be somewhat decreased. Patients with Banti's disease and secondary cirrhosis who have not yet reached the stage of portal stasis and ascites have a reasonably good outlook. Since, in the whole group, surgical exploration appears to be well tolerated, perhaps it should be considered more often, especially in view of the possible relation of splenic and cholecystic disease to cirrhosis. No doubt omentopexy or ligation of the venous channels communicating with the esophageal veins, as performed by Walters, could be done with greater prospect of benefit in compensated cases.²⁸ We feel that either a history of hemorrhage or the finding of collateral venous circulation may constitute a definite surgical indication in compensated cirrhosis of this type. The presence of jaundice or a history of intermittent episodes of jaundice are almost equally important in this connection, since in the jaundiced cases the possibility of a previously unsuspected stone in the common bile duct must always be kept in mind. Any mention of a surgical approach to hepatic cirrhosis of this type will perhaps be regarded as radical, however, we feel that these cases should not always be dismissed with the statement that nothing can be done. For instance, if patients have an alcoholic background and a history of hematemesis, the question of a Talma-Morison omentopexy and ligation of collateral venous channels connecting with the esophageal plexus should be seriously considered. Excellent clinical results have been obtained by this procedure, and failures have been chiefly due

to the very advanced state of the disease at the time of operation. Splenectomy may also be considered in this connection, it is performed too late in many instances and may offer far more in the latent case of cirrhosis, particularly if there is a history of hematemesis and anemia, with moderate or low degrees of retention of dye. It is apparent that surgical procedures in these latent or compensated cases should be considered more seriously in the early stage than in the advanced or decompensated stage.

CONCLUSION

The fact that most of the known causes of diffuse disease of the hepatic parenchyma are in themselves preventable or controllable must be emphasized. The medical profession should lower its threshold of suspicion relative to cirrhosis of the liver, center its attention on the earlier stages of hepatic disease, and search for evidence when the history and clinical and laboratory data are suggestive rather than clearly indicative of its presence. In all probability it is in this stage of the disease that further progress may be expected along lines of preventive medicine and treatment.

THE INCIDENCE OF FEMORAL HERNIA FOLLOWING REPAIR OF INGUINAL HERNIA—ECTOPIC RECURRENCE

A PROPOSED OPERATION OF EXTERNAL AND INTERNAL HERNIORRHAPHY

EDWARD RAYMOND EASTON, MD
NEW YORK

Various forms of hernia are liable to develop after any intra-abdominal operation. Direct hernia has occurred following operation for oblique inguinal hernia and occasionally, though rarely, after an inguinal operation for femoral hernia. In such cases there probably existed a small congenital diverticulum of the peritoneum, which was overlooked at the time of operation. The increase in intra-abdominal pressure due to reduction of the inguinal hernia, together with the stretching and weakening of Hesselbach's triangle caused by the deep sutures, may be sufficient to bring on a direct hernia.

Femoral hernia, likewise, occasionally appears after operation for inguinal hernia. In this case, the increased size of the femoral opening due to the pulling upward of Poupart's ligament in the course of repair of the inguinal hernia may be an etiologic factor.

During the past seven years I have observed four cases of femoral hernia following repair of inguinal hernia by the Bassini method, and one case was mentioned to me by Dr. Ellsworth Eliot, my chief at Knickerbocker Hospital, who has allowed its publication here.

CASE 1—A woman, aged 28, with well developed musculature, was operated on for oblique inguinal hernia, which extended slightly below the external ring. Eighteen months afterward, a swelling appeared below the inner extremity of the scar, which was called a recurrence by the family physician. On operation it proved to be a femoral hernia the size of a small orange. Palpation of the inguinal region through the neck of the sac showed a firm scar with no indication of bulging.

In discussing this matter with the chief medical examiner of the New York State Department of Labor,

Dr. Raphael Lewy, I found that the condition is not so rare as a survey of the literature for the past eighteen years has indicated. During this period, only two cases are mentioned. One is reported as follows by Taylor,¹ who collected the results of operations for inguinal hernia performed at Johns Hopkins from 1899 to 1918.

CASE 2—A man, aged 37, was operated on for indirect bilateral inguinal hernia on Aug. 8, 1910. The conjoined tendons were good on both sides. On the left side high ligation of the sac was done with heavy silk, the cord was not transplanted, and the cremaster muscle was drawn under the internal oblique muscle. There was no sac on the right side, prehermal weakness was noted. The cord was not transplanted and closure was done similar to that on the left side. Healing occurred on both sides by first intention. There was a small direct recurrence on the left side about one year later, and a femoral hernia on the right side two years later. Operation was performed on these hernias eight years after the first operation and the foregoing conditions were confirmed, there being a small rent in the aponeurosis of the right side through which a little fat protruded.

The second case is reported by Studinsky,² who believed that the hernial repair, which was performed in this case according to the method of Girard,³ was an etiologic factor in the development of the femoral hernia. The history, however, suggested a preformed sac, such as a dimple or diverticulum, because of the patient's having femoral hernia on the other side.

CASE 3—A man, aged 49, was admitted to the Central Prison Hospital at Kiev, Russia, in January, 1926. A few years previously he had an operation for left inguinal hernia and left testicular tumor. The growth had been removed and had recurred on the same side lower down. In the left inguinal region, below the inguinal ligament, a reducible tumor was found, from 6 to 7 cm. in diameter. Above the inguinal ligament, parallel to the inguinal canal, was a scar approximately 6 cm. long. An irreducible tumor in the right scrotal area was 15 cm. long and 10 cm. wide. A second and much smaller growth occupied the region of the inguinal canal 2 cm. above the inguinal ligament. It had a tympanic sound and crackled on reposition. The diagnosis was left femoral hernia, right inguinal hernia and right hydrocele.

Girard's herniotomy for right inguinal hernia was done and Winkelmans' operation for hydrocele, local anesthesia being used. Recovery occurred by first intention. The muscles, Poupart's ligament and the aponeurosis of the external oblique muscle were found to be weak. Permission to perform an operation for the femoral hernia was refused.

About a month later, a small femoral hernia appeared on the right side. The diagnosis was bilateral crural hernia.

Operation was then done on the left femoral hernia, by removal of the hernial sac. Recovery occurred by first intention. Two months later operation was done on the right femoral hernia, at which time examination showed no recurrence above or below the inguinal ligament after left herniotomy.

The following are the cases which came under my own observation.

CASE 4—J. S., an employee of the New England Panama Hat Company, was operated on at Flower Hospital, in 1926, for a reducible right inguinal hernia complicated by a hydrocele of the cord. The hydrocele was removed at operation and a hernioplasty done. A year later, after a fall, a right

femoral hernia developed. The patient was operated on by another surgeon, who confirmed the diagnosis and found no inguinal hernia present.

CASE 5—J P was operated on at Lexington Hospital in 1926 for bilateral incomplete inguinal hernia, each hernia being about the size of a plum. This case especially typified the relaxed abdominal walls and wide open external rings that were present to a greater or less degree in all the cases in this

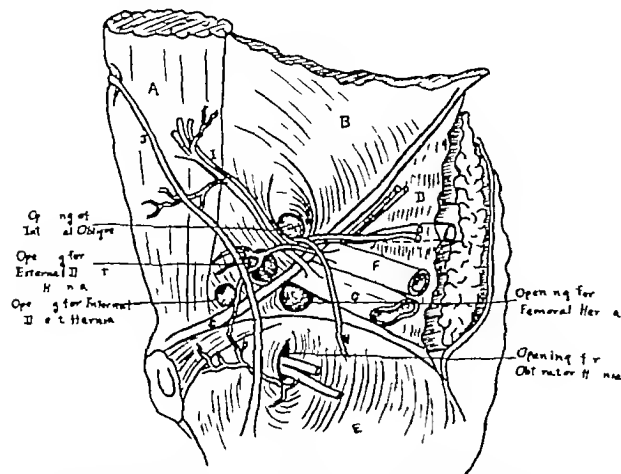

Fig 1—Various sites for hernia in the inguinal and femoral regions (Modified after Ferguson). series. Double femoral hernia developed within three months after the inguinal repair, and an operation was performed by another surgeon at the Hospital for Ruptured and Crippled.

CASE 6—S B was operated on at the Lexington Hospital in 1926 for indirect right inguinal hernia. Repair of this lesion was followed within three years by the development of a direct hernia, which was operated on, a right femoral hernia appearing three months later.

CASE 7—B M was operated on at the Fordham City Hospital in 1928 for right inguinal hernia. Within two or three months right femoral hernia developed. The patient was operated on by another surgeon and was observed only casually by me during a subsequent examination.

In May, 1929, I saw a patient at Broad Street Hospital with an epigastric hernia about the size of a small plum 2 inches above the umbilicus. There was also an impulse in the right inguinal region, and in the right femoral region was a mass which suggested a fatty tumor, as no impulse could be elicited on coughing. The epigastric hernia was repaired with a side-to-side overlapping of the fascia. An incision was then made in the inguinal region, and after the external ring had been dissected off a search was made for a sac. None was found, although there was a slight bulging of Hesselbach's triangle, as in direct hernia. An investigation of the supposed fatty tumor below Poupart's ligament disclosed that it consisted of a mass of peritoneal fat which had protruded through the femoral canal (not an uncommon finding in femoral hernia), with a distinct femoral sac about $2\frac{1}{2}$ inches in length. After removal of the sac, the double purse-string operation for obliteration of the femoral canal was done. Closure of the inguinal field was then made by overlapping the external aponeurosis with two rows of sutures, which permanently closed the external ring after transplantation of the cord.

The presence of a femoral hernia simulating the symptoms of an inguinal hernia in this case raised

the question of the possibility of an undiscovered femoral hernia in the other cases reported. It seems probable, however, that no femoral hernia existed in any of these cases at the time of the original operation, and that only a dimple or diverticulum of the peritoneum then present in the region of the femoral canal might have predisposed to the development of the subsequent femoral hernias.

A recent review of the work of Banerjee⁴ in operating on hernias through the abdominal approach reveals that of 200 abdominal operations performed by him and his associates only one failed to show a dimple, or a slight diverticulum in one or both inguinal regions (fig 1). In one instance a well defined congenital sac was discovered in a child 6 years old in whom no hernia had been suspected.

It is not unlikely that the existence of such a dimple or diverticulum, in itself a predisposing factor to the development of an actual hernia, has not received adequate attention and that if such a condition is disclosed in the course of any abdominal operation it should be corrected by Banerjee's procedure. It seems, however, that the cure of inguinal or femoral hernia does not lie solely in the internal herniorrhaphy but that it must be supplemented by some external method. By such a combined method, recurrence becomes less likely than when either procedure is used alone. The following operation is therefore suggested for use in selected cases, particularly those in which the patients have flabby or fat abdominal walls.

METHOD

The inguinal region is exposed through an incision from a point half an inch above Poupart's ligament, at the junction of its outer and middle thirds, downward and inward to a point half an inch above the spine of the pubis, whence the incision is extended across the midline transversely for the distance of 1 inch (fig 2). If the operation is for a double

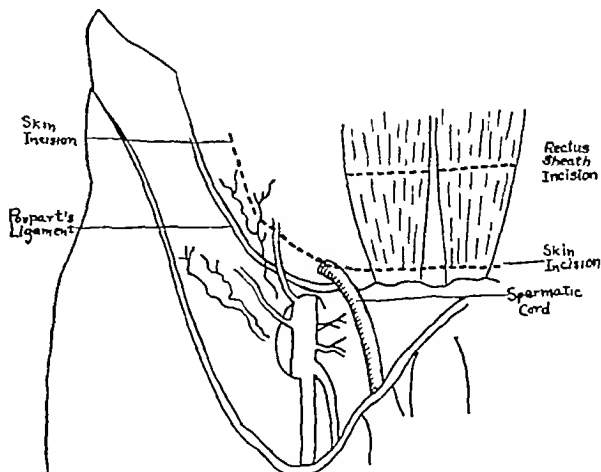

Fig 2—External view of inguinal region showing incisions.

hernia, the incision is continued in like manner on the other side. The incision is deepened to and through the aponeurosis of the external oblique, dividing the external ring in the direction of its fibers.

The procedure from this point depends largely on whether an adherent sac or contents are found after the sac is dissected free from the cord. If the sac is dissected free without

⁴ Banerjee, P. Intra-peritoneal Herniorrhaphy in Inguinal Hernia. Surg. Gynec. & Obst. 54: 706 (April) 1932.

difficulty or without adherence of the contents, the rectus sheath is then incised transversely according to the Pfannenstiel method at a point above the crest of the pubis in line with the internal ring. This is easily done by retracting the upper flap of the skin incision.

The transverse incision thus described is never longer than the breadth of the sheaths of both recti. In fact, it need be no more than $2\frac{1}{2}$ inches long (fig 2).

The peritoneum is then opened in the midline and the internal opening of the hernia dealt with by inversion of the hernial sac into the abdomen, all of the sac except a fringe or margin about three fourths of an inch wide being trimmed off. A purse string suture is then placed in the neck of the sac and tied within the abdominal cavity (fig 3 A). The free edge of the sac then remaining is turned back and tacked down throughout its circumference by interrupted catgut sutures through the peritoneum, so as to form a plug or button-like structure (fig 3 B).

After this procedure, the peritoneum is grasped laterally to this area with several Kocher clamps and sutured over the preceding layers of the hernial sac (fig 3 C).

If, however, the sac has been found adherent and prolonged into the scrotum, it is dissected free at the internal ring sufficiently to allow a cuff 2 inches in length to be inverted into the peritoneal cavity, where it can be treated in the same manner as described. If any contents, such as omentum, intestine or bladder, are found in the sac, it might be of distinct value to open the peritoneum through the Pfannenstiel

COMMENT

A somewhat similar operation was suggested by La Roque some years ago. He opened the peritoneal cavity well above the hernia, thus giving an excellent exposure of the vas deferens and bladder and assuring a high removal of the sac. The usual Bassini incision is made, and the hernial sac and cord are exposed. The fibers of the internal oblique and transversalis muscles are separated an inch above their lower margins, and the peritoneum is opened above the neck of the sac. If the muscles are thinned, they may be retracted upward. The hernial contents are examined and dealt with from the abdominal side. A finger is passed into the sac to aid in freeing it up to a point within the internal ring. Forceps are inserted in the sac, and the lowest portion is grasped and inverted into the abdominal cavity. The sac and redundant peritoneum are pulled upward and sutures are passed through the peritoneum an inch above the internal ring, which is completely obliterated. Each of these sutures includes a portion of the original peritoneal incision. The sac is excised, and the split muscle fibers are sutured together. The inguinal canal is closed in the usual manner, with or without transplantation of the cord, and the superficial fascia and skin are sutured.

Theoretically, this operation seems to be subject to the disadvantage that it does not permit inspection of all possible hernial sites. It also has a tendency to weaken adjacent muscular structures and fails to strengthen the region of the internal opening of the hernia.

Kocher and McEwen dealt with the sac by transplanting it, Kocher into the subcutaneous tissues and McEwen extraperitoneally under the internal oblique muscle. Kocher's procedure is not now used, but McEwen's method of dealing with the stump of the sac has in its favor that it transplants the neck of the sac to a point less liable to recurrence.

Ferguson believed that the cause of inguinal hernia was a deficiency of the internal oblique and transversalis muscles at Poupart's ligament and in 1899 devised an operation to correct this condition. This is the same as the modified Bassini operation up to the point of closure. The cord is left undisturbed and the internal ring, which consists of transversalis fascia, is narrowed by catgut sutures. The internal oblique and transversalis muscles are stitched to the shelving edge of Poupart's ligament. The aponeurotic flaps are overlapped and sutured, and the external ring is restored. The subcutaneous tissues and skin are closed in the usual manner.

By not disturbing the cord, this procedure has the evident advantage of avoiding injury to the vas and adjacent blood vessels and nerves. Also, the cremaster muscle remaining substantially in its normal position may assist in curing the hernia, since its action tends to have a shutter-like effect on the inguinal canal. However, the operation does not prevent the chance of recurrence, which the author admits did take place.

Banerjee's operation, carried out through the midline incision, may ultimately be followed by diastasis of the rectus muscles. For this reason, the midline incision is much less desirable than the Pfannenstiel incision, which, in the absence of infection, is rarely followed by any abdominal weakness.

Banerjee claimed that but little could be done externally without damage to muscle, blood supply and

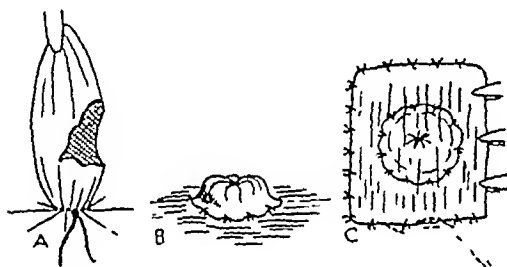

Fig 3—A the sac is resected a cuff three fourths inch wide being left. B the cuff is reversed on itself and sutured to the peritoneum. C a fold of adjacent peritoneum is plicated over the button like structure.

incision at once before attempting resection of the sac, in order to observe the condition on the inside of the cavity and deal with it from that angle.

The original incision is then closed by the method advised by Pfannenstiel, the rectus sheath being sutured with interrupted chromic sutures.

After the rectus sheath has been repaired the inguinal operation is continued with whatever form of repair seems appropriate for the individual case. In general, a type of operation such as Ferguson's⁶ seems appropriate for indirect hernia, while the Halsted method, with the use of a flap of rectus sheath in case of a deficiency of the conjoined tendon, would be better for the direct hernia. Occasionally, transplantation of the cord according to the method of Bassini, Andrews or Scott is more suitable to the individual case.

I believe an effort should be made to correct, by interrupted or continuous sutures, the deficiency of the transversalis fascia both at the internal ring and at Hesselbach's triangle and to repair the damage done to the cremaster muscle by dissection of the sac. Also, the overlapping of the external oblique muscle strengthens the hernial repair, no matter what type of operation is carried out. The incision is then closed with interrupted or continuous sutures, according to the surgeon's preference.

5 Some practical difficulty may be encountered in inverting the sac. This may be facilitated by placing two sutures through the tip of the sac which can readily be tied to the blades of short curved sponge forceps and the sac drawn up through the internal ring into the peritoneal cavity. Before one inverts the sac it might be well to place a purse-string suture round the neck from the outside which may be tied after inversion. This closes the orifice while the internal herniorrhaphy is being done and also reinforces the second purse-string suture to be made on the inside.

6. Ferguson A. H. *Technic of Modern Operations for Hernia* ed 2 Chicago, Cleveland Press 1912

nerves The fact that the vast majority of hernias have been cured by the external operation alone, however, appears in part to do away with this objection

From the standpoint of the onset of hernia, it would seem a good surgical principle to begin to set up a wall against its reformation at the site of exit in the abdominal wall On the other hand, Banerjee's operation will not be universally adopted because of the feeling that the plication of peritoneum does not adequately prevent recurrence at the point where the former hernia existed

If, in the course of operation, a femoral hernia is found, it must be attacked either by internal herniorrhaphy or by the Moschowitz operation, with an extension of the incision downward, if necessary, as described by Moschowitz in his original communication The occurrence of a femoral hernia, or at least of the prehernial dimple, is probably more frequent than is ordinarily reported

Dr Lewy, whose experience in examining these cases has been unique, believes that several factors contribute to the formation of these femoral hernias occurring after inguinal repair

1 The contents of the inguinal hernia having been returned to the abdomen, the abdominal cavity is too small to hold them

2 Repair of inguinal hernia, suturing the conjoined tendons and internal oblique and transversalis muscles to Poupart's ligament, may have had a tendency to elevate the ligament in certain cases in which relaxation of this structure is already present, thus increasing the patency of the femoral canal

3 There is individual predisposition to hernia by reason of fat, flabby muscles and relaxed ligaments, also certain cachectic states, including tuberculosis and malignant growths, in which hernia is not uncommonly found

Consideration of these interesting observations of Dr Lewy's seems to justify the conclusion that a femoral hernia was not present at the time of the inguinal operation in any of the four cases observed by me, but had developed later as an ectopic recurrence, just as direct hernia follows repair of the indirect types

To obviate such a sequel, the operation herein proposed is designed to set up a barrier both internally and externally which seems unlikely to yield, and in that event recurrence would at least be uncommon It may be said to present the following advantages

1 High removal of sac

2 Allowing for

(a) Thorough inspection of the bladder, omentum, intestine or other contents of the sac

(b) Complete repair of all the layers of the abdominal wall

(c) Removal of the appendix, or the performance of other surgical procedure through the midline not incompatible with the repair of hernia

(d) Tightening up by plication of any preformed hernial sac (dimple, diverticulum or unclosed funicular process) at any other hernial site (direct or femoral)

3 Putting a cork, or plug, in the neck of the hernial sac

361 West Fifty-Seventh Street.

TYMPANIC PLEXUS NEURALGIA

TRUE TIC DOULOUREUX OF THE EAR OR SO-CALLED
GENICULATE GANGLION NEURALGIA CURE
EFFECTED BY INTRACRANIAL SECTION
OF THE GLOSSOPHARYNGEAL NERVE

FREDERICK LEET REICHERT, M.D.
SAN FRANCISCO

Twenty-four years ago, an operation was performed in the now famous case of Clark and Taylor¹ for a tic douloureux of the left ear and external auditory canal which had been present for two years It was a paroxysmal intermittent pain without known cause with "not only a stabbing pain in front of the ear, but also a steady pain in the depths of the ear, on the anterior wall of the external meatus At times there was a moderate degree of neuralgic pain in all three distributions of the trifacial and in the occipital region" A number of neurologists were forced to conclude, guided by the fact that Hunt's² zoster zone of the geniculate lay just in the interior of the auricle and external canal, that the lesion was a true tic douloureux of the geniculate system of the facial nerve Under ether anesthesia by a unilateral cerebellar approach, Taylor divided the sensory part (pars intermedia) of the seventh nerve intracranially He was forced also to divide the facial and part of the acoustic nerve Immediately after operation all pain ceased except for a period of two hours on the twelfth day, when the patient suffered "severe pain in the left ear which closely resembled the pains before operation A slight redness of the external auditory canal, observable before operation," disappeared shortly after operation Six years later the patient was seen by Dr Crile, who found that she had remained free from attacks and that the facial palsy had disappeared

History—A woman aged 31, a telephone operator, with a history almost identical with that presented in the case of Clark and Taylor, was referred to the Stanford University Clinic, Oct. 3, 1932, because of a severe pain in the left ear In 1921, she had been forced to dispense with ear phones for a short time because of a painful left concha She had no further difficulty until the spring of 1932, when a sensation of drawing and discomfort in the left upper part of the face was noticed, which by August had extended from the cheek to the forehead and occipital region A coryza at this time was followed in two days by sharp stabbing pain deep in the external auditory canal, causing her to shriek out and grab her ear The paroxysms came frequently each day except for an interval of twelve days following the injection of the sphenopalatine ganglion with procaine hydrochloride Subsequent injections gave no relief Besides the excruciating lancinating pains in the auditory canal there were at times an itching of the upper anterior wall of the meatus, aching pains in the left side of the face, nose, eyeball and parieto-occipital area, and sensitiveness in the mastoid and pretragal regions Nothing seemed to induce the attacks and there was no salivation during the paroxysms

Because of injection and swelling of the posterior superior wall of the external auditory meatus, which was sensitive efforts were made to eradicate any foci of infection. Sinuses were opened and treated teeth were extracted, the sphenopalatine ganglion was injected with procaine hydrochloride and

From the Department of Surgery Stanford University School of Medicine.

1 Clark L P and Taylor A S True Tic Douloureux of the Sensory Filaments of the Facial Nerve Cure Effected by Physiologic Exstirpation of the Geniculate Ganglion J A M A. 53 2144 (Dec 25) 1909

2 Hunt, J Herpetic Inflammation of the Geniculate Ganglion J Nerv & Ment. Dis 34 73 1907

alcohol, trichloroethylene inhalations and galvanism were tried, and the left sympathetic chain at the seventh cervical and the first and second thoracic vertebrae was injected with procaine hydrochloride, but attacks continued even while the effects of the procaine were evident. Although there were never any herpetic lesions in the ear, or facial palsy, the diagnosis concurred in by the neurologists and others was geniculate ganglion neuralgia or geniculate tic douloureux.

During the first week in December the paroxysms came every one to three minutes. Sedatives gave little help and the patient begged for relief. With a case before me identical with that of Clark and Taylor's, I asked permission, if necessary, to cut the eighth and seventh nerves in an effort to identify and cut the pars intermedia of the seventh. The patient agreed to the operation under local anesthesia in order to aid in locating this sensory filament of the facial nerve.

Operation.—December 10, the unilateral cerebellar approach of Dandy³ was performed under local anesthesia. The left eighth, ninth and tenth nerves were easily identified and lay separate from one another. The seventh and eighth nerves coursed together, the seventh lying anteriorly, being difficult to distinguish from the eighth. When this bundle of seventh and eighth nerve fibers was gently touched and moved, the patient stated that she felt pain in the auditory canal but it was not the tic pain. The ninth nerve was then touched which caused her to shriek and to exclaim that this produced the tic pain. Four times the seventh and eighth nerves were gently moved and each time she had pain in the auditory canal and four times the ninth nerve was gently moved and each time she shrieked because of a stabbing paroxysmal pain in the ear identical with that which had afflicted her for four months. The glossopharyngeal nerve was then cut and the patient fell asleep on the operating table.

Postoperative Course.—More than four months has elapsed since the operation and she has not felt any suggestion of the tic pain, nor has the pain in the face and occipital region returned. Anesthesia of the ear or its external canal could not be demonstrated after the operation. The patient located the pain that was produced when the seventh and eighth nerves were touched during the operation to the cartilaginous portion of the anterior wall of the external auditory meatus, and the tic pain, produced when the ninth nerve was touched was referred to the bony part of the anterior wall of the external auditory canal.

Sensation, as tested by Dr. E. C. Sewall, was lost over the left soft palate, over the pharyngeal wall from 2 cm. within the eustachian tube to the tip of the epiglottis and over the posterior third of the tongue, where taste was also absent. This distribution of sensory and gustatory loss was the same as that observed in three other cases of intracranial section of the ninth nerve for the ordinary glossopharyngeal tic douloureux,⁴ and is in agreement with the observations of other operators such as Dandy,⁵ Stookey⁶ and Bailey,⁷ and contrary to the observation of Fay,⁸ who felt that this distribution of anesthesia followed section of the vagus.

Salivary secretions were simultaneously collected from the parotid and submaxillary glands and observed from the sublingual glands in this patient ten days and ten and thirteen weeks after operation. These measurements of salivary secretion in conjunction with those

obtained from two other cases sixteen months and two and a half years after intracranial division of the ninth nerve, and the results obtained in four patients in whom the chorda tympani had been avulsed just distal to the facial nerve, from three days to four months after carefully observed radical mastoidectomies, led Poth and me⁹ to conclude that the secretory fibers of these glands accompany both the seventh and the ninth nerves. This is contrary to the accepted teachings, which state that the secretory fibers of the sublingual and submaxillary glands accompany the seventh only.

COMMENT

This case, in which a preoperative diagnosis of geniculate ganglion neuralgia had been made, was found at operation to have the tic-like pain consistently reproduced only when the glossopharyngeal nerve was touched. It was concluded, therefore, that the patient had a tic douloureux of the tympanic branch of the glossopharyngeus (Jacobson's nerve or plexus), and since her symptoms were identical with those of the patient of Clark and Taylor, their case undoubtedly was likewise a Jacobson's nerve neuralgia.

It is interesting to note that Clark and Taylor's patient for two hours on the twelfth postoperative day suffered severe pain in the ear, which closely resembled the pain before operation. Mills¹⁰ and Kidd¹¹ felt that the cure secured by these authors did not prove Ramsay Hunt's contention of the existence in man of cutaneous sensory fibers of the seventh nerve, and Mills went so far as to suggest, apparently correctly, that "the effects of decompression in such cases should not be overlooked."

I am forced to conclude that there are at least two types of neuralgia or tic douloureux of the glossopharyngeal nerve. Over forty cases have been reported in the literature of the ordinary or complete glossopharyngeal neuralgia, which is characterized by paroxysmal attacks of lancinating pain, usually starting in the tonsillar region or base of the tongue and frequently radiating to the ear, often accompanied by salivation and induced by eating, talking or swallowing or by other movements of the pharynx and tongue.

Partial involvement of the glossopharyngeus or Jacobson's nerve tic douloureux is a rare neuralgia of the tympanic branch of the glossopharyngeal nerve which has been regarded in the literature as a tic of the sensory filaments of the seventh nerve and is more commonly termed geniculate ganglion neuralgia. It is characterized by paroxysms of stabbing pain in the external auditory meatus, often associated with other pains in the face and postauricular region, not induced by talking, eating or swallowing, and not associated with salivation.

SUMMARY

Primary tic douloureux of the ear was found at operation, performed under local anesthesia, to have been caused by a lesion of the tympanic nerve or plexus of Jacobson, and was cured by intracranial division of the glossopharyngeus.

The one case of a tic douloureux of this branch of the glossopharyngeal nerve, recorded in the literature as operated on, was diagnosed as a tic douloureux of the

sensory filaments of the seventh nerve but was probably cured by the decompressive feature of the cerebellar operation rather than by the section of the seventh nerve

Partial or complete involvement of the branches of the glossopharyngeal nerve has led to the differentiation of at least two types of neuralgia of this nerve

The common or complete tic douloureux of the glossopharyngeus is characterized by paroxysms of lancinating pain starting in the tonsillar fossa or base of the tongue, generally radiating deeply in the ear, accompanied by salivation and induced by swallowing, talking or other movements of the throat and tongue

The partial or Jacobson's plexus tic douloureux of the glossopharyngeus is characterized by paroxysms of lancinating pain in and about the external auditory canal and is not induced by any movements of the pharynx or tongue and is not accompanied by salivation. This neuralgia has heretofore been considered as a geniculate ganglion neuralgia

Intracranial division of the glossopharyngeal nerve has cured both types of these neuralgias

TRICHOMONAS VAGINITIS IN CHILDREN

LESTER E. FRANKENTHAL, JR., MD

AND

ALFRED J. KOBAK, MD

CHICAGO

The literature concerning *Trichomonas vaginalis* and its association with a definite syndrome of leukorrhea and vaginitis has become quite voluminous during the past decade. This type of vaginitis in recent years is frequently found in adults, both in private and in clinic patients. Whether this increase is actual or relative remains to be determined. Undoubtedly one is more alert in studying the vaginal secretions for these protozoa whenever their presence is suspected. Bland and his associates¹ have thoroughly reviewed the literature concerning *Trichomonas* in women. However, our own scrutiny of the literature has shown this type of vaginitis to be very rare in children. We have been unable to find a report detailing any author's personal experience with *trichomonas vaginitis* in children. In fact, Kleegman² in 1930 makes the following assertion: "The organism has never been found before the onset of menstruation, but is frequently found during pregnancy and after menopause." In 1931, the article of Cornell and his associates³ makes brief mention of H. W. Hottenstein of Akron, Ohio, who had a 3 year old patient in whom a *trichomonas vaginitis* was found. In 1932, we⁴ published a brief communication of what appears to have been the first authentic case report of *trichomonas vaginitis* before the onset of menstruation.

4 Frankenthal L. E. Jr and Kobak, A. J. Trichomonas Vaginalis Occurring Before Menstruation. *Am. J. Obst. & Gynec.* 23: 450 (March) 1932

The organism was first described in 1837 by Donne⁵ and in 1896 Dock⁶ was the first to report it in the United States. It belongs to a group of flagellates that are closely related morphologically. It is demonstrable in the mouth, the intestine and the urinary tract, as well as in the vagina. Lynch⁷ in 1915, considered the organisms found in the mouth and vagina to be identical. Hegner⁸ has been able experimentally to transmit the trichomonads in monkeys from the intestine to the vagina and believes that a similar route may be the etiology of vaginal infections in man. Andrews⁹ however, has ascertained that prolonged culturing of *Trichomonas vaginalis* changes it so as to resemble *Trichomonas hominis* (the gastro-intestinal type). Bland¹ states, however, that these results must yet be checked by further investigation. These organisms, when found in the intestinal tract of children, are reported to be definitely pathogenic and give rise to a dysenteric syndrome¹⁰. The flagellates are described by Hegner and Talaferro¹¹ as being from 12 to 26 microns in length and from 6 to 18 microns in width. They vary greatly in size and are accepted to have four flagella and an undulating membrane on one side. They are readily detected on a fresh warm slide of the material, which has been diluted with physiologic solution of sodium chloride, and are easily visualized with a high power dry objective among clumps of pus cells, usually clinging to them and distinguishable from the latter only by their vigorous motions.

At the present time there are many who are uncertain as to the exact pathogenic category into which to place this organism. Whether it is the sole causative factor or one of association is a question. Still others are of the opinion that it is a harmless saprophytic agent. It is not within the province of this report to take any part or to offer any theory as to what role this organism plays in the production of a vaginitis. We are, however, of the opinion that a characteristic type of vaginitis is invariably associated with its presence and that a clinical cure seems to follow when the therapy has succeeded in eliminating these flagellates.

There is still much to learn concerning this organism. Only recently, Stein and Cope¹² and Davis¹³ have improved the methods for obtaining cultures. These authors, as well as others, are still unable to obtain a pure culture of *Trichomonas vaginalis*. No doubt when this is done and their life cycle determined, together with more exact data as to their habitats, one may hope for a more uniform and precise type of therapy.

Regarding the treatment for adults, much may be said, but most of it in a negative way. The various therapeutic agents sponsored by different authors are

too many to enumerate Greenhill,¹⁴ among others, has advocated "scrubs" with liniment of soft soap (tincture of green soap) followed by drying as a basis for treatments. For lack of anything more satisfactory, and because it does succeed in improving the patient and even giving a lasting cure in some cases, we have accepted this form of therapy. We might say, however, that while the majority of women are almost immediately benefited, some will persist in showing trichomonads over a long period, in spite of the therapy.

In the outpatient clinic of the Michael Reese Hospital during the past two years, four cases of trichomonas vaginitis in children were detected. All the patients were between the ages of 11 and 14 years. Three of these cases were seen before the onset of menstruation. In each patient a history of profuse, irritating vaginal discharge was elicited. On examination, we found in all four a bubbly, foamy, gray to green discharge which bathed the external genitals and irritated the surrounding skin. Vaginoscopic examination showed the vagina to be definitely affected, and the summits of the rugae contained small punctate hyperemic spots. The latter were especially noted around the cervix.

REPORT OF CASES

CASE 1—M S., a girl, aged 10 years 11 months, was admitted to the Vaginitis Clinic, Feb 20, 1931 complaining of a vaginal discharge of over a year's duration. She appeared pale and underweight. Examination showed the external genitalia to be bathed in a foamy, grayish, purulent discharge with irritation of the adjacent skin. The vagina as seen through the infant vaginoscope appeared reddened, and the tips of the rugae in the vicinity of the cervix contained punctate injected spots. Direct examination of the discharge revealed numerous motile flagellates among clumps of leukocytes. The gram stain was negative for gonococci in several examinations. Cultures on Sabouraud's medium were negative for yeasts. The blood examination showed 78 Sahli units of hemoglobin and 10,200 white cells, the differential count was normal. The routine urinalysis revealed trichomonads which proved to be a vaginal contamination. Vaginal cultures were positive for the presence of flagellates, but the fresh stool cultures were negative (method of Stein and Cope).

Owing to the age of the patient and the presence of an intact hymen, the usual vigorous treatment given to adults could not be undertaken. For the first month the patient received weekly applications of silver nitrate with daily installations of 2 per cent mercurochrome. During the next four weeks, mercurochrome was supplanted first by astringent douches and then by potassium permanganate 1:5000. Hoping to obtain some of the success noted in the adults, we tried liniment of soft soap "scrubs" and vigorous drying, using a gauze cloth on the common applicator stick. The discharge gradually decreased, and while the trichomonads frequently, periodically, disappeared from the secretions, they would reappear. The patient's attendance at the clinic was irregular and there was no satisfactory cooperation in the home therapy.

CASE 2—H S., a girl (a sister of patient 1), aged 14 years 7 months, undernourished and pale, had been ailing since an attack of double pneumonia with secondary meningeal involvement. Her basal metabolism ranged from minus 25 to minus 34, and she was subject to attacks of petit mal. She was first seen in the Vaginitis Clinic, May 1, 1931, when the following observations were made. A frothy mucoid vaginal discharge contained numerous trichomonads among clumps of pus cells, the skin surrounding the vulvar orifice was slightly irritated and bathed by this mucous discharge, the vagina contained a few punctate injected areas while the cervix was normal. A blood study showed that the Kahn and Wassermann tests were negative, the hemoglobin 78 Sahli units, the red cells 4,330,000 and the white cells 9,750. The differential

count was normal. The urine and stool cultures were negative for trichomonads. Cultures of the vaginal secretions were positive for *Trichomonas vaginalis* but negative for yeast. The patient had had only one menstrual period, six months before the treatments were begun, and then her menses gradually became cyclic. Her personal hygiene was very poor. The clinic treatment consisted in liniment of soft soap "scrubs" and drying. Daily irrigations of 1:5000 potassium permanganate were prescribed for home treatment, which were to be given even on the days she menstruated. However, as in the first cited case, a lack of cooperation in clinic attendance and home treatments was associated with slow progress in a year of therapy. The patient is, however, now improved but not entirely cured of and free from trichomonads.

CASE 3—R B., a girl aged 12 years 7 months, pale and undernourished with irregular cervical gland scars on the left side of the neck, was referred from the pediatric group because of spastic colon, backache and vaginal discharge. Her menses did not begin until nine months after the diagnosis, which was made in the Vaginitis Clinic, June 12, 1931. The following observations were made at that time. A bubbly, vaginal discharge which irritated the external genitals was present, the labia were covered with smegma, the hymen was ruptured, and the vagina and cervix were hyperemic and contained punctate injected spots. The vaginal secretions revealed motile trichomonads among many clumps of white cells. The hemoglobin was 67 Sahli units, the red blood count was 4,350,000, the white blood count, 6800. The differential count showed 64 per cent polymorphonuclear leukocytes and 36 lymphocytes. Urinalysis was negative. The treatment in this case, because of the ruptured hymen, permitted more liberty in the vigor of the liniment of soft soap "scrubs" and exposure of the vaginal mucosa for gauze drying. Silver nitrate, 5 per cent, was applied to the vaginal mucosa and glycerin tamponades were used. At home the mother was instructed to irrigate the vagina with potassium permanganate 1:5000, daily. However, her visits were irregular and the mother was indifferent in her cooperation. After one year of poor attendance, attributed to conflict with her school work, a renewed effort was made for more regular treatment during her summer vacation. Metaphen in oil, 1:1,000 was then substituted for glycerin tamponades. Definite clinical improvement was noted in her subsequent visits, and her discharge seems to be almost cleared up, but trichomonads are still present, though in fewer numbers.

CASE 4—B C., a girl, aged 11 years, well developed with a previous history of vaginal discharge during infancy, complete data of which were lacking was first seen in the Vaginitis Clinic, April 1, 1932, and the following observations were made. A moderate frothy vaginal discharge, which bathed the irritated external genitals, was present, the vagina and cervix contained injected punctate spots and were immersed in this bubbly discharge and the wet spread examination of the vaginal secretions showed many trichomonads and pus cells. Blood examination showed hemoglobin 75 Sahli units, a count of 4,340,000 red cells, and 9,900 white cells, the differential count showing polymorphonuclears, 55 per cent, lymphocytes 40 per cent, and eosinophils 5 per cent. Urinalysis was negative. Local internal treatment was not used in this case. The mother however, was instructed to cleanse the external genitals with a bland soap on a soft cloth and to administer ergosterol daily. Rapid improvement was then noted, the condition progressively cleared up, and in seven weeks the hanging drop was negative for trichomonads. Since then she has had little or no discharge, and the vaginoscopic examination has showed progressive improvement in the vagina and cervix. On two subsequent visits there was a recurrence of the trichomonads, but in very small numbers. Her condition at the present time is very satisfactory.

COMMENT

The diagnosis of trichomonas vaginitis is easy to make. Whenever a case of vaginitis presents a bubbly or foamy leukorrhea, the possibility of trichomonads being present should be foremost in mind. The diagnosis is easily confirmed by examining a drop of

¹⁴ Greenhill J. P. Vaginal Discharge Due to *Trichomonas Vaginalis*, *Am J Obst. & Gynec.* 16: 870 (Dec.) 1928.

the secretion diluted with warm physiologic solution of sodium chloride under high dry power. Vigorous motile flagellates are seen isolated or among clumps of white cells. They vary in size, shape and degree of motility.

It is surprising that, with many juvenile vaginitis clinics, *Trichomonas vaginalis* infections should be so rarely reported in the literature. Only one other case of this type of vaginitis has come to our attention, but not directly from the physician who treated the girl. It seems that the popular concept of childhood vaginitis is so much associated in the minds of physicians with gonorrhea and nongonorrheal bacterial infections as the underlying etiologic basis that it is only for these organisms that the physician looks. With the clinical picture of trichomonas vaginitis in mind, one may readily confirm a suspicion of its presence. With this thought, every well organized vaginitis clinic should always have a microscope handy, as part of its equipment, and accessible for use. In this way, we believe that more of these cases during childhood will be brought to light.

Retrospection of the four cases presented shows that certain conditions were common to all. The character of the discharge and the peculiarity of the appearance of the vaginal mucosa when examined with the electrical vaginoscope were constant. The ages of our patients were rather close, ranging from 11 to 14 years. Three of them had not menstruated, and one had had only one period before the diagnosis was made. From Jan. 1, 1931, to Sept. 1, 1932, our vaginitis clinic admitted for treatment sixty-one new patients, ranging in age from infancy to 14 years. It is striking that the four patients with trichomonas infections should have been in the puberal age. The degree in which puberty may play a part is uncertain, but it is accepted that certain constitutional and local changes take place, which may in some way be contributing factors.

Patients 1 and 2 are sisters. It was likewise noted that their mother also harbored trichomonads in the vagina. Here the question of contact arises as a source of this infection. That contact may play a part in other forms of childhood vaginitis is conceded by many. Regarding its dissemination through male contact, Riba and Perry¹⁵ have shown this organism to be found also in the prostatic secretions. Capek¹⁶ reports the presence of trichomonads in a man with nongonorrheal urethritis whose wife harbored them in the vagina, cervix and urethra. While it remains for some zealous investigator to establish the contagiousness of this disease by Koch's postulates, there is a definite suspicion that contact dissemination may play a role in some way. We believe in advising regulations similar to those imposed in venereal infections, viz., sleeping isolation, care in the usage of the toilet and towel, bathing and the like.

Another common factor is the questionable hygiene of our patients and their pale and undernourished appearances, which might have contributed in a degree to the lowering of their resistance. Sharman,¹⁷ in his paper on leukorrhea in virgins, considered this to be a factor in nongonorrheal vaginitis and possibly in trichomonas. He gave viosterol, which seemed to be beneficial in many of his cases. We have always aimed to improve the poor hygiene of our patients through our

social service bureau and have prescribed vitamin D for them and advised a well balanced diet.

The local treatment was, however, very difficult. The presence of the small introitus and a narrow hymenal ring made the usual treatment accorded to adults hardly possible. In addition, the cooperation on the part of the patients' clinic attendance and the home treatment in three of our patients was very poor, despite our social service follow up. The course of the vaginitis in the first three cases cited was prolonged. It has been our observation, in nongonorrheal forms of vaginitis, that withholding the local treatment together with improvement of the patient's local and general hygiene has been productive of better results. Therefore, in case 4, liniment of soft soap "scrubs" and vaginal irrigations were dispensed with. For this patient, ergosterol was prescribed, and her mother was urged to keep the patient's external genitals in a good state of hygiene by daily cleansing of the labial folds with a bland soap on a soft cloth. Her progress was more rapid and favorable than the others. Whether this form of treatment is best remains to be determined in a study of more cases. It is hoped that with this report more cases of childhood vaginitis will be inquired into for the possible association of *Trichomonas vaginalis*, and that a more rational and successful therapy will be forthcoming.

SUMMARY

1 Four cases of *Trichomonas vaginitis* during or before puberty, selected from a large group of children of all ages, occurred during puberty, this period of life was therefore considered as a possible contributing factor. Three of our patients were prepubescent and the other had had only one menstrual period prior to her admission.

2 The diagnosis of this condition is easy to make. Routine vaginoscopic and hanging drop examinations should be made in all suspected cases.

3 The local treatment in children is very difficult and unsatisfactory because of the vaginal introitus and infantile state of the genitals.

4 Improvement of local and general hygiene together with a well balanced diet is very beneficial. The one patient limited to these measures made the most satisfactory progress.

5 The course of this infection is prolonged in childhood and it is more difficult to effect a cure than in adults.

104 South Michigan Avenue—30 North Michigan Avenue.

The Case of the Medium Margery—Disclosures said to present evidence of fraud in the production of certain spiritistic phenomena in the case of Margery, the Boston medium are reviewed in the May issue of the *Scientific American*. Since 1926 the most prominent phenomenon in Margery's manifestations has been the production of thumb prints by a ghostly hand, which Margery and her supporters claimed belonged to a spirit named Walter. In March, 1932, E. E. Dudley, an investigator, is said to have discovered that the prints which for six years were produced as those of the spirit 'Walter' were actually those of a living Boston dentist. It is said that the dentist signed a set of his own prints and acknowledged before witnesses that he gave them to Dudley. Walter Franklin Prince, author of the article in the *Scientific American*, is research officer of the Boston Society for Psychic Research. He says that common sense measures for proof of the phenomena have been repeatedly refused by the medium. The writer considers that the "ectoplasmic" hand has been proved to be of flesh and blood manipulated under draperies, and that this exposure throws doubt on all of the medium's claims thus demolishing the entire case.

THE DIATHERMY TREATMENT OF
DEMENTIA PARALYTICA

MICROSCOPIC CHANGES IN TREATED CASES

WALTER FREEMAN MD PHD

THEODORE C FONG, MD

AND

S J ROSENBERG, MD

WASHINGTON D C

The disadvantages of malaria in the treatment of dementia paralytica are manifold. The strain is difficult to keep going outside of large clinics, the fever is uncontrollable, immunity often develops so quickly that a full course of fever is impossible, and serious complications or even death may result from the induced disease. The prospect of being able to secure equal results with greater control and less danger is therefore engaging, and with this in mind, artificial fever provoked by diathermy has been introduced into a number of clinics, and almost universally favorable results have been reported. From a survey of the literature, table 1 has been constructed.

We have been unable to reproduce these results. Diathermy was introduced at St Elizabeth's Hospital in August, 1928, and has been used in fifty cases, the experiment being concluded in June, 1932. Forty of

The treatment of the others was interrupted by complications after from one to nine periods.

The application of the treatment was marked by considerable difficulties. Some of the patients became very restless during the period of rising temperature, and two instances of rather extensive second degree burns followed consequent shifting of the electrodes. During the period of high fever later on the patients became quiet and not infrequently developed muscular twitchings and in some instances actual convulsive seizures. There was marked prostration after most of the treatments with listlessness and inability to take food. Convulsive seizures were observed to be much more

TABLE 2—Results of Diathermy Treatment in Fifty Cases

Clinical Type	Improved*	Unimproved	Died
Agitated	2	5	1
Depressed	8	1	2
Demented	0	20	11
Total	10	26	14

* Four of the ten patients reported as improved were progressing favorably under tryparsamide at the time diathermy treatment was administered and two have received malaria treatment with three and twenty two paroxysms respectively.

frequent in the diathermy cases than they were in the corresponding malaria cases. Moreover, while it was common in malaria cases to observe noticeable improvement from one paroxysm to the next, with abating confusion and better cooperation, such a phenomenon was not witnessed in any of the diathermy cases. Indeed, patient 4 showed quite the opposite. He was in such good condition before the diathermy that ground parole was considered but even during the course of diathermy his condition changed and the nurses' notes indicated that he was becoming more confused and restless. Later he deteriorated with unusual rapidity in spite of arsenical therapy, dying in eight months.

In many cases, some benefit resulted from preliminary antisyphilitic therapy, and following diathermy this benefit was maintained, but only by the continuous use of tryparsamide. When the drug was omitted, prompt relapse ensued. This is another finding at odds with the malaria cases. In several scores of control cases no therapy was given following malaria, yet improvement was usually maintained and sometimes continued progressively after subsidence of the induced disease.

Facilities for treatment were such that only four patients could be handled during a period of three weeks, and patients with dementia paralytica were being admitted considerably faster than that. In contrast, we have frequently seen a ten bed ward filled to capacity with patients, all of them in the acme of fever, quiet, with one nurse and an attendant able to care for the lot. Had the results warranted it, additional facilities for diathermy could have been made available, but the treatment was finally abandoned in 1932, not on account of technical limitations but because of poor results.

In explaining the poor results we are inclined to absolve the machines and the technic. Milliamperage was adequate and the fever was as high as safety permitted. If the febrile conditions of the malaria could be duplicated artificially, they were complied with in the handling of the cases. The patients were not of the most favorable type. Eighty per cent of our patients were Negroes, and neurosyphilis in the colored race is possibly more malignant than in the white race. While only a few patients were markedly deteriorated, most

the patients were Negroes who had been unsuccessfully inoculated with malaria, and ten were white males, seven of whom had received a course of malaria without much benefit. Almost all the patients had been treated previously with specifics, and twenty of them received tryparsamide and bismuth salicylate afterward. In forty-four cases a full series of diathermy treatments was administered, the temperature being raised to 104 plus during a period of from two to five hours.

From St Elizabeth's Hospital
Read before the American Neurological Association May 11 1933

were of the dementing type of dementia paralytica that makes a poor showing with any form of treatment

The results of diathermy treatment in the fifty cases are presented in table 2. Two of the deaths resulted from thermic fever that could not be controlled, and another from convulsive seizures shortly following the first period of treatment. The other eleven patients lived from two to thirty months, dying usually of the cerebral disease with terminal bronchopneumonia or status epilepticus, very much in the manner of the ordinary untreated case of dementia paralytica. Few of them, however, reached the stage of cachexia. This,

TABLE 3—Serologic Results Following Diathermy*

	Normal	Improved	Unchanged
Wassermann reaction	26%	14%	60%
Spinal Wassermann reaction	3%	13%	74%

Colloidal gold	5%	42%	53%

* Twenty seven cases one year or more following diathermy

again, is a feature of unfavorable comparison with the results observed in malaria. While malaria fails to arrest the process of dementia paralytica all too frequently, the patients are apt to die of some intercurrent disease, hepatic, vascular, infectious, and less than half of those succumbing later present dementia paralytica as the outstanding cause of death.

The serologic results in patients treated by diathermy were quite encouraging in the earlier phases, but relapses occurred in a large proportion of cases. A year ago we estimated a 20 per cent improvement, but at the present time the proportion maintaining improvement has been reduced to 8 per cent. The results of this study are given in table 3.

PATHOLOGIC CHANGES

In the reports in the literature up to the present time we have found no mention of the pathologic changes in the cases of dementia paralytica treated by dia-

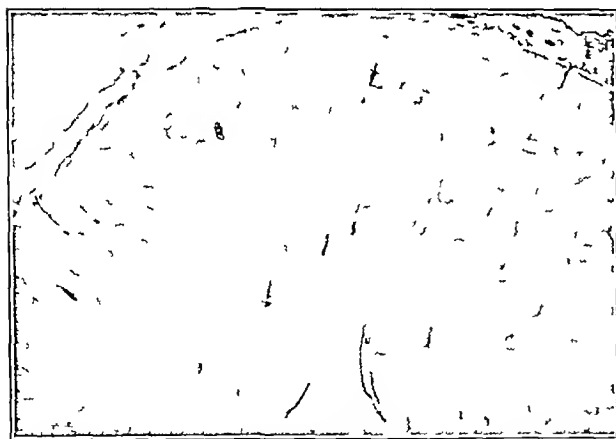

Fig 1 (case 1)—Cerebral cortex, showing pronounced perivascular infiltrations and some disorder in the cortical architecture

thermy. These represent an important control feature and have been one of the chief bulwarks of the malaria treatment. In a majority of cases, malaria brings about a demonstrable arrest of the inflammatory and degenerative processes that are going on in the brain. We are able to report on the postmortem examination of nine cases treated by diathermy. One of the patients died during the administration of diathermy, and a

second patient five months after a single treatment interrupted by convulsive seizures. These are therefore not well suited for the purpose of ascertaining any possible arrest. Nevertheless, the indications of extrusion of the infiltrating cells along the vascular sheaths into the meninges, and of organization of the perivascular exudate as described in previous contributions

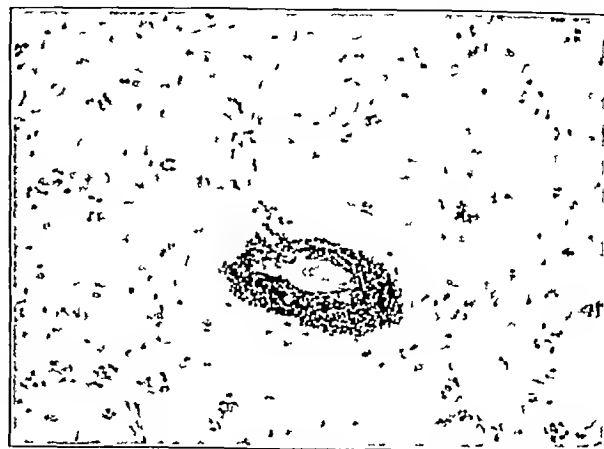

Fig 2 (case 1)—Large cuff of plasma cells about small vein in caudate nucleus

regarding the immediate effects of induced malaria,¹ are lacking in these two diathermy cases. They present merely the usual appearances of the brain in dementia paralytica.

In six cases² death resulted in from three to ten months following diathermy, and the clinical features and pathologic changes are given in abstract.

REPORT OF CASES

CASE 1—M. W., a Negro, aged 46, was admitted, Dec. 5, 1928, and died, Aug. 14, 1930. The psychosis began in December, 1927, with hypochondriacal complaints but did not become severe until the summer of 1928, at which time there were confusion, disorientation and euphoria. The pupils were inactive to light and the knee and ankle jerks were absent. The serologic examination gave results typical of dementia paralytica. Before the diathermy treatment he received 29 Gm of tryparsamide and 3 Gm of bismuth salicylate. He was in good condition and received ground parole following this. In September, 1928, he ran away and returned in April, 1930, much the worse for wear. He then received ten diathermy treatments, the temperature averaging 104.4. Subsequently however, he showed rapid deterioration both physically and mentally, and four days before death developed intractable convulsions with terminal hypostatic pneumonia. The duration after diathermy was four months.

Necropsy revealed atrophy of the cerebral cortex with disordered lamination and polarity, and rather marked gliosis with abundant perivascular round cell infiltration and extensive new vessel formation (fig 1). In addition to the alterations in the cerebral cortex there were unusually severe perivascular infiltrations in the basal ganglia (fig 2) and some compact nodules with apparent vascular occlusion that were rather reminiscent of miliary gummas. It seemed, indeed, that the

1 (a) Freeman, Walter. Malaria Treatment of General Paralysis. Histopathologic Observations in Fifteen Cases. J. A. M. A. 88: 1064 (April 2) 1927. (b) Malaria Treatment of Paresis. Extracerebral Pathology and Its Bearing on the Modus Operandi. Am. J. Syph. 14: 326 (July) 1930.

2 On the day this paper was presented another diathermy patient died thirty months after treatment. Admitted in December 1928 with typical clinical and laboratory observations, she did well under tryparsamide and bismuth therapy, even being allowed short visits. Following diathermy in November 1930, she was maintained in the same condition until March 1932, when deterioration recommenced and convulsive seizures occurred. Necropsy disclosed extreme cerebral atrophy with characteristic meningeal and ependymal changes and a positive Spatz reaction.

inflammatory manifestations were more marked in this case than in the average untreated patient.

CASE 2.—J W, a Negro, aged 32, was admitted, Feb 8, 1930, and died, Dec. 10, 1930. He was an employee of the hospital and neurologic observations were picked up before the psychosis developed. In December, 1929, he became excited and confused and tried to harm himself. The pupils were unequal and irregular and were inactive to light, there were perioral tremors and slurring speech, and the knee jerks were absent. The serologic examination gave results characteristic of dementia paralytica. Neither before nor afterward did he receive any antisyphilitic treatment, and malaria inoculation failed. Ten diathermy treatments were given, the rectal temperature averaging 104.8. For a few weeks the patient was in good condition and enjoyed parole. In June, 1930, however, convulsions developed, they were repeated in series in September and October, and he died with bronchopneumonia. The duration after diathermy was nine months.

Necropsy disclosed relatively slight inflammatory infiltrations in the cerebral cortex, but more extensive ones in the basal ganglions and thalamus. Vascular proliferation was a pronounced feature and the number of rod cells was definitely increased.

CASE 3.—S A, a Negro, aged 31, was admitted March 31, 1929, and died, Aug 1, 1932. The syphilitic infection was established at the age of 20 years, he drank to excess and took drugs, and was admitted from Fort Leavenworth. The psychosis began acutely three days after his sentence began, with confusion, irritability and visions of women in his cell at night. The pupils were sluggish and there were tremors about the mouth with slurring of speech. The patellar and achilles reflexes were diminished the others were increased. The serologic examination gave results characteristic of dementia paralytica. He received 58 Gm of tryparsamide and 285 Gm of bismuth salicylate and a malaria inoculation but had no chills. The spinal fluid improved under chemotherapy but the clinical condition did not. In September 1931, he received ten diathermy treatments without complications. Still there was no clinical improvement and convulsions developed July 28, 1932. Death was associated with the development of bronchopneumonia. The duration after diathermy was ten months.

Necropsy showed some thickening, fibrosis and inflammatory infiltrations in the meninges, with marked disorder in cortical

Fig 3 (case 3)—Extensive perivascular infiltrations in cerebral cortex together with vascular proliferation, gliosis and meningeal thickening.

lamination, and severe gliosis. The inflammatory infiltrations about the vessels were considerably more marked than those of the average untreated case of dementia paralytica (fig 3). Rod cells were especially abundant, and examples of neuronophagia were quite frequently observed. Especially notable was the severity of involvement of the optic tectum. Not only was the aqueduct more than half closed by glia proliferation, but the perivascular infiltrations in the central gray matter and in the colliculi were unusually intense (fig 4). The Purkinje

cells of the cerebellum showed more or less complete degeneration and vacuolization. The Spatz reaction for waste iron was positive.

CASE 4.—A C, a Negro, aged 31, who was admitted Nov 11, 1930, and who died, Sept 20, 1932, was picked up by the police after a drinking bout, with some stolen property in his possession. He was euphoric and had grandiose delusions, admitted auditory hallucinations, and showed defects in judgment.

Fig 4 (case 3)—Partial closure of aqueduct by ependymitis with marked inflammation in the tectum mesencephali.

Memory and orientation were preserved. There were coarse tremors of the mouth and hands, with exaggerated reflexes. The pupils reacted fairly well to light and in accommodation. The serologic examination gave strongly positive results. He received two unsuccessful inoculations with malaria, 17 Gm of tryparsamide and 28 Gm of bismuth salicylate. During the latter part of 1931 he was in very good mental and physical condition and ground parole was permitted. In January, 1932, he received ten diathermy treatments, said he felt worse afterward, and rather rapidly developed irritability and confusion, became depressed, attempted suicide and finally refused to keep his clothes on. His face and ankles became edematous and his temperature fell below the registration point. He was so restless and uncooperative that he could not be handled, and died, apparently, of hypothermia. The duration after diathermy was eight months.

Necropsy disclosed acute duodenal ulcers and syphilitic aortitis. The brain was the seat of marked inflammatory and degenerative manifestations of dementia paralytica, with broad collars of cells around the vessels and hordes of rod cells (fig 5). In the lamina pyramidalis of the hippocampus Hergert preparations showed the processes of round cells more or less completely enveloping the shadowy outlines of ganglion cells (fig 6). The Spatz reaction was positive.

CASE 5.—R. L, a Negro, aged 53, who was admitted, Feb 18, 1932 and who died, Jan 28, 1933 was arrested for patrolling one of the government buildings under the belief that President Hoover had ordered him to kill the foreigners. He was expansive, loquacious and overactive and he talked in a rambling, incoherent manner. Neurologic examination disclosed characteristic disorders of the pupils, speech and reflexes, and the serologic examination gave positive results. The urine contained sugar. He assaulted a patient and received a black eye. His only treatment other than diathermy was 13 Gm of bismuth salicylate. He received ten diathermy treatments soon after admission but showed no improvement remaining disturbed and assaultive. June 2, 1932, he had a convulsion following which he was confused and noisy, quieting down gradually to his former state and the convulsions recommenced, December 3. He had lost greatly in physical strength although his diabetes was inactive, the blood sugar being normal. He remained in bed until another episode of convulsive seizures ended with bronchopneumonia. The duration after diathermy was ten months.

Necropsy revealed marked inflammatory infiltrations in certain parts of the cerebral cortex, with atrophic processes in others. The perivascular infiltrations were even more prominent in the basal ganglions and midbrain.

CASE 6—J T, a Negro, aged 34, who was admitted April 12, 1928 and who died, April 15, 1932, was exceedingly restless and uncooperative on admission. His trouble had begun with slur-

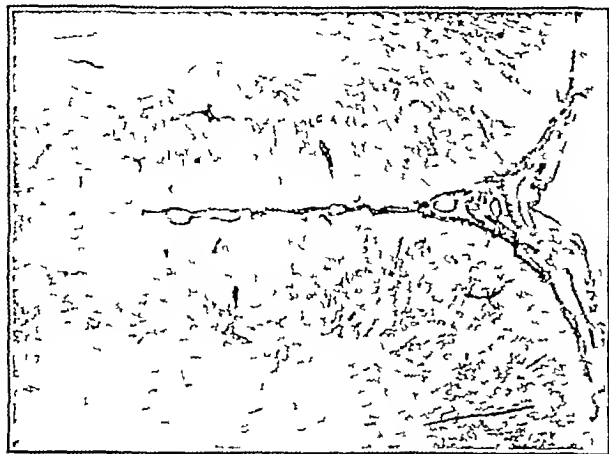

Fig 5 (case 4)—Cortical atrophy and condensation with meningeal and perivascular inflammation. This represents more marked inflammatory changes than are observed in the average untreated case of dementia paralytica.

ring speech and trembling hands in 1926, but not until November, 1927, did he have a definite break, at which time he had a fainting attack followed by loss of the power of speech. The pupils were large and irregular and reacted slightly to light, there were marked tremors about the mouth and speech was unintelligible. The tendon reflexes were markedly exaggerated and there was swaying in the Romberg position. The serologic examination gave results typical of dementia paralytica. He was given 112 Gm of tryparsamide and 416 Gm of bismuth salicylate, and was inoculated with malaria on two occasions without result. In December 1931, he received ten diathermy treatments but he remained much dilapidated. His finger became infected. He chewed the dressings and swallowed the medicaments; this set up an extensive cellulitis with septicemia from which he died. The duration after diathermy was three months.

Necropsy disclosed very marked atrophy of the brain, with an abundance of cerebrospinal fluid. There was an infarct in the left supramarginal gyrus with thrombosis of an arterial branch in the sylvian fissure. Histologically there was persistent inflammation of marked degree with an enormous number of hypertrophied microglia cells.

CASES IN WHICH IMPROVEMENT WAS OBSERVED

We are a little hesitant yet to pronounce the improved cases arrested. Among the ten so listed, only four cases may be thus considered following diathermy alone, since six patients had received, in addition, bismuth compounds and tryparsamide and two of these had previously had malaria, one a full series of twenty-two paroxysms. This patient had recovered sufficiently to be discharged as having effected a social recovery following malaria but was later readmitted on account of seizures. These two patients were slightly improved following the subsequent diathermy. Finally, in the four cases not already more or less under control with malaria and antisiphilitic therapy, tryparsamide was given after the diathermy treatment. An additional sixteen patients received tryparsamide and bismuth compounds after diathermy without manifesting any particular improvement. It was noted in more than

one of these cases that the condition remained fairly stationary as long as the drug was given but that prompt relapse followed its omission, even if only for a short period. The total sustained improvement attributable to diathermy alone therefore sinks to zero. Six treated patients were discharged from the hospital as improved, and two as unimproved, while twenty-eight remain in the hospital.

COMMENT

The substitution of diathermy for malaria in the treatment of dementia paralytica has, in our hands, met with almost complete failure. While it is admitted that the patients were not of the best type, that the treatment may not have been sufficiently prolonged and that the use of arsenical therapy as an adjuvant was not pushed to the possible limit, the fact remains that, in comparison with the results from malaria, the benefit to the patients has been far from impressive. The difference becomes more notable as the period of time elapsed after the treatment becomes longer. In our opinion the early reports on the diathermy treatment of dementia paralytica were published after too short a period of observation, especially since even now it is less than five years since Neymann and King and Cooke first began their experiments.

We are unable to pronounce any judgment on the widely heralded use of radiotherapy in the treatment of the same disease. This procedure, like that of diathermy and of therapeutic malaria, will have to go through a period of clinical trial and histologic verification before its true value in neurosyphilis becomes established. We deplore especially the broadcasting of premature reports through nonprofessional periodicals, although the hurried publication of first results in medical journals is also to be regretted. Even in our diathermy cases we do not feel that the course of the patients under our care has reached a stationary phase, although we have a sufficient number of five year and

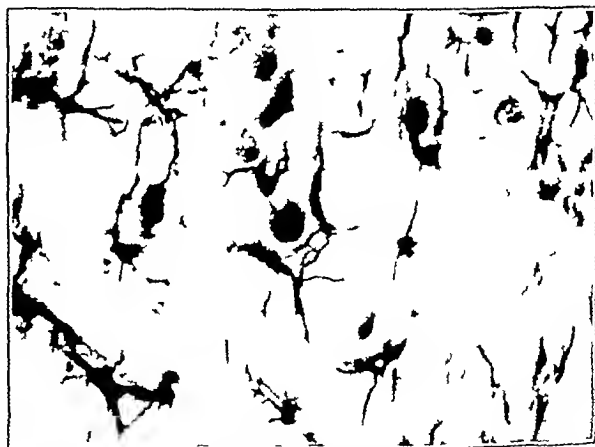

Fig 6 (case 6)—Ganglion cells faintly outlined surrounded by processes of hypertrophied microglia, in hippocampus.

ten year records in the case of therapeutic malaria to be able to pass fairly accurate judgment.

This is not the place to enter on a discussion of the method by which malaria works in neurosyphilis, but, at least from our experience, it would not seem to be the bodily temperature reached, because the same or even higher temperatures are reached in diathermy. Whether it is the activation of the reticulo-endothelial

system in malaria that is absent in diathermy or whether there is more efficient forced drainage of the neural parenchyma during the febrile paroxysm of malaria, as suggested by one of us^{1b} is still a matter for further consideration

CONCLUSIONS

We do not wish to express ourselves too strongly concerning the poor results in cases of dementia paralytica submitted to diathermy, feeling that possibly some factor in the handling of our case has been neglected. However, we feel justified in stating that diathermy is not an altogether innocuous treatment but is sometimes dangerous, especially in individuals subject to convulsive seizures. We have observed no case of improvement in patients subjected to diathermy alone, and, in many cases, previous and subsequent treatment by preparations of arsenic and of bismuth has not prevented the patients from deteriorating.

The high percentage of deaths (28) in our small series over a period of four years contrasts very unfavorably with the results obtained in malaria.

The histologic control in six cases has revealed persistent inflammation in every case

CONGENITAL ATRESIA OF THE ALIMENTARY TRACT

DIAGNOSIS BY MICROSCOPIC EXAMINATION OF MECONIUM

SIDNEY FARBER, M.D.

BOSTON

My purpose in this paper is to describe a simple procedure for the early diagnosis of congenital atresia of the esophagus or intestine by means of microscopic examination of the meconium.

Congenital atresia of the intestine has been recently treated in its various aspects by Ladd.¹ He emphasizes the great importance of early recognition and surgical intervention. The methods of roentgenologic diagnosis of esophageal atresia have been described by Vogt.²

The procedure I am reporting has proved of value and has the advantages of simplicity and accuracy. It is based on the well established fact that a considerable part of the bulk of meconium is made up of swallowed amniotic sac contents. Amniotic sac contents, in addition to the amniotic fluid, consist of vernix caseosa, lanugo hair and cornified epithelial cells, all derived from the skin of the fetus. The origin of meconium, according to Feldman,³ is as follows:

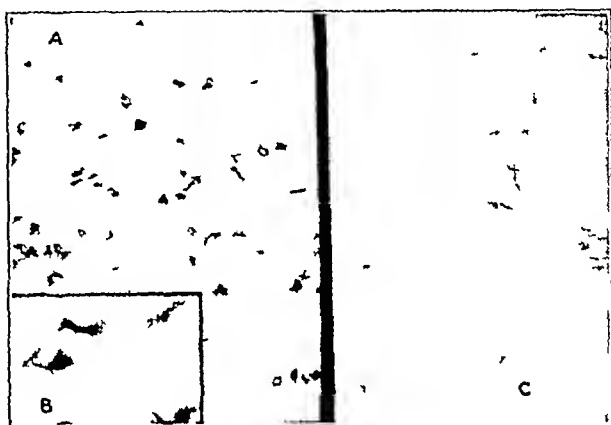

- 1 Swallowed liquor amni, with its added ingredients
- 2 Bile and pancreatic secretions
- 3 Intestinal secretions
- 4 Desquamated intestinal epithelium.

Congenital atresia of the alimentary tract occurs at some time before the third month of intra-uterine life.⁴ Vernix caseosa and cornified epithelial cells are not present in the amniotic sac contents in large amounts until the last few months of pregnancy. It is therefore

apparent that, should congenital atresia be present at any point in the alimentary tract, none of the amniotic sac contents will be found in the meconium. In such cases, gross examination of the meconium has not yielded much information because of the variation in the normal appearance of meconium.

There are a few references in the older literature to examination of the meconium in such cases, but no reference has been found concerning the procedure recommended here, although the general underlying principles have been noted. Feldman³ mentioned, for example, that "in those rare cases where the esophagus is congenitally occluded the component parts coming from the liquor amni, viz, vernix caseosa and lanugo hairs, are not found."

The most constant and easily recognizable constituents of that part of meconium derived from swallowed amniotic sac contents are cornified epithelial cells. The ease of recognition of the cornified cells in the amniotic sac contents and the significance of their presence have

A low power view of smear of normal meconium showing large numbers of cornified epithelial cells (methyl violet stain). B high power view of A. Cornified epithelial cells are slightly turned on edge. C low power view (same magnification as in A) of smear of meconium from a patient with congenital atresia of the small bowel. Total absence of cornified cells may be noted. Only mucus is seen.

been amply studied in another connection (aspiration of amniotic sac contents in the lungs).⁴ These cells have no nuclei, are large and thin, and are often found slightly turned on edge. They resemble large scales. Cornified cells can be found in large numbers without difficulty in normal meconium. Since they are derived from the skin of the fetus and must be swallowed to appear in the meconium, their presence in the meconium is proof that the gastro-intestinal tract is patent throughout. The absence of cornified epithelial cells from the meconium is proof that a point of atresia is present somewhere in the alimentary tract.

The cornified cells may be recognized in unstained preparations of meconium, after some experience. For accurate work, however, I have developed a method for the recognition of cornified epithelial cells in smears of meconium. I was aided by the fact that cornified cells, after being stained by Sterling's gentian violet (of the ordinary gram stain for bacteria) and decolorized by acid alcohol, retain the stain, while all other cells are decolorized.⁵ To lessen difficulties in microscopic exam-

From the Department of Pathology of the Harvard Medical School and of the Children's Hospital and the Infant's Hospital.

mation of a smear of meconium due to the large amounts of fatty material present, I have found it helpful to treat the smear with ether or xylene before staining. The procedure is as follows:

- 1 Make a thin smear of meconium on a glass slide
- 2 Place the slide either immediately or when dry in a dish containing ether for from one to five minutes, until fatty substances disappear
- 3 Dry in air for a few seconds
- 4 Stain for one minute with Sterling's gentian violet.
- 5 Wash in running water
- 6 Decolorize with acid alcohol
- 7 Dry and examine

The cornified cells stain deep blue. All other cells are decolorized.

A prettier stain is obtained if methyl violet is used instead of gentian violet. With methyl violet, from five to fifteen minutes of staining is required, and very light decolorization with acid alcohol is sufficient. Gentian violet, however, stains more quickly, the stain does not deteriorate, and the cornified cells resist acid alcohol decolorization much more effectively than when stained with methyl violet, thereby permitting greater ease of recognition of the cells.

SOLUTIONS FOR STAINING⁶

1 *Sterling's Gentian Violet for Gram's Stain*

Gentian violet	5 Gm.
Alcohol (95 per cent)	10 cc.
Aniline	2 cc.
Water	88 cc.

This solution keeps remarkably well.

2 *Acid Alcohol*

Hydrochloric acid	1 cc.
Alcohol (70 per cent)	99 cc.

3 *Methyl Violet*

There are two permanent stock solutions from which the aniline methyl violet solution can be made when desired.

Solution I

Absolute alcohol	33 cc.
Aniline	9 cc.
Methyl violet in excess	

Solution II

Saturated aqueous solution of methyl violet

Stain with

Solution I	1 part
Solution II	9 parts

This mixture should be made up fresh every time and will keep at most for fourteen days.

SUMMARY

1 A simple procedure for the early diagnosis of congenital atresia of the esophagus and intestine is based on the constant presence in normal meconium of cornified epithelial cells, which are derived from the skin of the fetus and which are swallowed with the other amniotic sac contents to contribute to the formation of meconium.

2 Microscopic examination of smears of normal meconium, when treated with ether, stained with Sterling's gentian violet and decolorized by acid alcohol reveals large numbers of cornified epithelial cells. All other cells are decolorized by this method, thus permitting easy recognition of cornified cells.

3 The absence of cornified epithelial cells in smears of meconium is proof of the existence of congenital atresia of the alimentary tract.

300 Longwood Avenue.

CHRONIC INFECTIIONAL EDEMA

FRANKLIN A. STEVENS, M.D.

NEW YORK

Ten years after Fehleisen¹ isolated the streptococcus from the skin lesions of erysipelas, Sabouraud² obtained cultures of streptococcus from patients with recurrent erysipelas and elephantiasis. Subsequent pathologic studies of the diseased tissues convinced both Sabouraud and Unna³ that the edema and fibrosis which they found in the microscopic sections were not the result of circumscribed obstruction to the lymphatics, as in filarial elephantiasis, but to local changes in the tissues. Although they disagreed in some particulars regarding the mechanism underlying the pathogenesis of the edema and fibrosis, they agreed that repeated streptococcal infections which kept the cells bathed in the products of bacterial disintegration that were not adequately drained away were responsible for the pathologic condition. While Sabouraud attributed the hypertrophy solely to streptococcal infection, instances of chronic or recurrent infections with staphylococcus⁴ as well as streptococcus⁵ causing similar edema and fibrosis have been reported since his original observations were published.

Since 1925 I have studied thirty-eight patients with recurrent infections resembling erysipelas. Half of these were infections of the extremities and half recurrent infections of the face. In all of the patients in whom extensive and permanent edema of the extremities was associated with recurrent erysipelas or lymphangitis, of whom there were five, the vascular and lymphatic circulation had been impaired by operations or disease prior to the onset of the infection. The impaired circulation and the inadequate drainage of the extremities in these patients had apparently lowered the resistance to bacterial invasion and increased the liability to subsequent edema. While an impaired venous or lymphatic circulation has seemed to be important in the pathogenesis of the edema occurring in the arm and leg, edema of the face has followed infections without similar predisposing circulatory disease. Neither the severity, the frequency nor the extent of the facial infections has had the least relationship to the development of the edema. Chronic infections of the sinuses have, however, appeared important in this respect. Four of the five patients with facial edema had infected antrums or ethmoidal sinuses. The importance of these infections is emphasized by the absence of similar infections among the fourteen patients in whom edema has not developed.

Isolated attacks of erysipelas differ in several respects from recurrent attacks. The isolated attacks are usually constitutionally more severe. While streptococcus can be aspirated from the margin of the inflamed area and is found in great numbers in the lymph spaces in microscopic sections in the usual infection, few bacteria are found in the recurrent disease. Amoss has been unable to recover streptococcus from

the margin of recurrent infections although he found a few bacteria in sections of the skin.⁶ All the infections he has reported were on the lower extremities, and all had dermatophyton infections of the feet through which infection entered the skin. Cultures from the areas of dermatitis showed hemolytic streptococcus in four of thirteen patients. In repeated cultures on twenty patients, I have obtained streptococcus by aspirating the inflamed margin during exacerbations of infection only four times. The paucity of bacteria in the recurrent form of the disease has led Amoss to suggest that the inflammation may be due, in some instances, to bacterial products draining through the lymphatics from the portal of infection rather than to actual invasion of the skin by bacteria. Repeated efforts were made to obtain streptococcus from all five patients with facial edema during reinfections, but cultures were obtained from only three, in one from the skin of the face, in one from the buccal mucous membrane, and in the third from the antrum. One of these patients also had a complicating staphylococcal infection. In the other two I never found hemolytic streptococcus, but *Staphylococcus aureus* was constantly present in the nose and sinuses, and, during exacerbations of the edema and inflammation, was recovered from small pustules appearing on the skin.

I was confronted with several problems in undertaking the treatment of these patients with infectional edema of the face. The circumorbital tissues were so edematous that the eyes were nearly shut, the sinuses of three of the patients were badly infected and required treatment and, in addition, varying degrees of fibrosis were present which would eventually require plastic operations. Fortunately, after the edema subsided, plastic surgery was found necessary in only one case. To prevent recurrent infections and to reduce the edema were the immediate problems.

Assuming that the pathogenesis of erysipelas was similar to scarlet fever in that immunity to both was antitoxic, Birkhaug⁷ has advocated the immunization of patients who have recurrent attacks, with toxic filtrates prepared with strains of streptococcus from erysipelas. Amoss⁶ also has treated patients with recurrent infections of the leg successfully with filtrates. His treatment was not confined to immunization, however, because all of his patients had epidermophyton infections of the feet which served as portals of entry for the streptococcus, and treatment of this eczema was instituted at the same time that immunization was begun. McGlasson's⁸ observation that recurrent erysipelas and cellulitis of the leg in patients with ringworm dermatitis of the feet could be controlled by curing the dermatitis without immunizing to streptococcus emphasizes the importance of treating the focus of infection and raises the question of the necessity for immunization. Among my patients with recurrent infections were some with dermatophyton infections similar to those reported by Amoss⁶ and McGlasson⁸ and others in whom no dermatitis or abrasion was found through which streptococcus might enter the skin. Many of the former infections have been controlled solely by healing the dermatitis, and the latter by immunization alone. But the patients with

facial edema and sinus infections have been more difficult to treat than those with uncomplicated recurrent infections. The infected mucous membrane lining the infected sinuses has presumably been as edematous as the overlying tissues of the face. Irrigation of the sinuses, permanent drainage and vaccines of streptococcus and staphylococcus have failed to reduce the edema or control the recurrent infections, but the sinus infections have improved, the edema has subsided and recurrent infections have ceased, following repeated inoculations with toxic filtrates, after the sinuses were adequately drained.

Both Birkhaug and Amoss have tested patients with intracutaneous injections of toxic filtrates of type strains of streptococcus prior to immunization. They then immunized with filtrates of strains to which the individual patient reacted. In our series this testing has often been unsatisfactory, because the reactions were faint, varied from time to time and, in patients with edema, have been almost uniformly negative. Since the cutaneous reactions failed to indicate the proper strain for immunizing the individual patient, a mixture of filtrates from three type strains has been used for inoculating the patients with streptococcal edema. Fortunately, staphylococcus filtrates have many of the properties of filtrates of streptococcus.⁹ Some strains produce a potent toxin if grown several days in proteose peptone broth in an atmosphere of carbon dioxide. These filtrates have recently been used in the treatment of furunculosis and acne.¹⁰ On account of the similarity between the streptococcal and staphylococcal infections with edema, toxic filtrates of staphylococcus have been employed in the patients with staphylococcal infections. Several series of inoculations have been given each patient. Beginning with dilutions of 1:200, subcutaneous injections have been given twice each week, increasing the dose gradually until 1 or 2 cc of undiluted filtrate could be tolerated. During the immunization a critical dose was reached, usually between 0.1 and 0.2 cc of undiluted filtrate, which caused redness, increased edema and swelling of the face. These reactions have been specific, occurring only with staphylococcus filtrates in staphylococcal infections, and with streptococcus filtrates in infections with streptococcus. If the amount of filtrate injected was reduced the reactions ceased, and subsequently, by gradually increasing the dose, 1 or 2 cc of undiluted filtrate eventually could be administered. Recurrences of infection occurred between series of inoculations. But with each series the edema and inflammation have receded until, at the present time, recurrences of infection have ceased and the faces are normal except for residual fibrosis. These patients have been tested intracutaneously also, with nucleoproteins of streptococcus and staphylococcus, with toxic filtrates and filtrates devoid of toxins, and filtrates devoid of toxin have been injected subcutaneously to evoke focal reactions. The details of the treatment are given in the following case histories.

REPORT OF CASES

CASE 1—J. K., a boy, aged 14 (fig. 1) in 1927 came to the clinic with a history of repeated attacks of erysipelas beginning in 1922. The first attacks had been so prolonged and so severe

that he had been admitted to several hospitals on account of the gravity of the constitutional symptoms. On one occasion erysipelas serum had been given with prompt relief, and on another the antrums were irrigated but records of these admissions with more detailed information could not be obtained.

When he was first under observation, the circumorbital tissues, the nose, the cheeks and the lips were intensely swollen and inflamed, with incrustations and excoriations of the palpebral fissures and of the nares. The lips, however, were the most prominent part of the face for, in addition to the edema, tremendous amounts of fibrous tissue had been formed until each lip was fully 3 cm thick. Cultures made from the nose, conjunctivae and throat showed both hemolytic streptococcus and *Staphylococcus aureus*. Although the antrums and ethmoids appeared infested in roentgenograms, the edema and excoriation of the nose prevented adequate treatment, though subsequently, after the edema had partially subsided, thorough irrigation was possible. The edema would partially disappear and then an acute inflammatory attack would occur, leaving the face in a much worse condition. Cultures taken from material aspirated from the upper lip during one of these exacerbations yielded the hemolytic streptococcus. The patient was tested with filtrates of erysipelas strains at this time with negative results, but on account of the history of the preceding

In February, 1933, he had an attack of tracheitis and pharyngitis. Hemolytic streptococcus was found in the throat and sputum at this time, but there was no recurrence of the erysipelas or of the edema.

CASE 2—M C, a girl, aged 14 (fig 3), was seen in the clinic in January, 1930. At 2 years of age, the skin of the neck and face was infected for six months, and from this time until she was 9, the lips, eyelids and cheeks were swollen constantly. The swelling was especially severe after colds, when papules appeared around the nostrils and eyes. At times a recurrent blepharitis denuded her eyelids of lashes. When she was first examined, the entire face was edematous. The upper lip and the circumorbital tissues were most markedly swollen and red, pitting on deep pressure. At intervals the swelling was so intense that the eyes could scarcely be opened and speech was difficult. The antrums were found infected with *Staphylococcus albus*, *Staphylococcus aureus* and *Streptococcus viridans*. The sinuses were irrigated and a vaccine of these bacteria was given, but even with this treatment she had three recurrences with fever and edema following colds. Reexamination of the sinuses showed insufficient infection to account for the edema.

In December, 1930, she was seen during an acute attack. The infection did not resemble erysipelas because the entire area previously affected had become uniformly swollen, without a definitely raised margin. Material aspirated from the inflamed skin grew no bacteria, but staphylococcus was obtained from several small pustules at the margins of the lids. The skin of her forearm was tested with toxic filtrates of streptococcus and staphylococcus, and with these nucleoproteins, without causing a local erythema. The association of streptococcus and staphylococcus in the preceding case led at first to treatment of the case as a mixed infection with both these bacteria.

Toxic filtrates of these two bacteria were administered until August, 1931, in gradually increasing doses. Small doses were administered without reactions, but as the dose was increased the face would swell, about twenty-four hours after the injection. The amount of filtrate given was increased, regardless of these reactions, until eventually a point was reached at which undiluted filtrate could be given without causing edema. A recrudescence of the infection occurred in November, 1931, so a series of inoculations was given during the subsequent winter. The edema and inflammation gradually subsided and, although the patient had several colds, her face was not swollen at the time. By 1932 (fig 4) the

edema and inflammation of the face had almost subsided. She was tested with large subcutaneous doses of streptococcus filtrate, toxic filtrate of staphylococcus, and filtrate devoid of toxin. The inflammation increased only after injections of staphylococcus filtrates. Since this was the only proved sensitization, a series of inoculations with this filtrate alone was begun. The edema was practically gone, if compared to the condition of the face when first under observation. No necessity for further treatment is anticipated after the current series of inoculations. This last series of injections with nontoxic staphylococcus filtrate has caused edema and eczema of the upper part of the face during the administration of doses of 0.1 to 0.2 cc of filtrate. Once edema and inflammation occurred after 0.005 mg of the nucleoprotein of staphylococcus. This eczema subsided after the dose was reduced.

CASE 3—Following a keratitis of the left eye in 1923, H G had periodic attacks of inflammation and facial swelling at intervals of about six weeks. During the first two years the attacks were severe, with fever, malaise and vomiting but later, when less frequent, these acute exacerbations were milder. Resolution was complete between the first attacks, but after 1928 the face was constantly swollen and inflamed.

The patient came to the clinic in 1929. The forehead just above the eyebrows, eyelids, nose, cheeks, paranasal folds and

Fig 1—Patient 1 prior to treatment, Feb 9 1927

Fig 2—Patient 1 Oct. 13 1932 subsequent to a plastic operation on the lips for the removal of fibrous tissue and desensitization with filtrates of hemolytic streptococcus and staphylococcus.

erysipelas he was immunized with a mixture of filtrates of three type erysipelas strains of streptococcus. He had no attacks until the late summer of 1928, after inoculations had been discontinued and, in the meantime, Drs Dunning and Parker had removed strips of fibrous tissue, measuring 2 by 5 cm, from both lips.

Microscopically, these sections were composed of dense edematous connective tissue with areas of degeneration beneath the mucosa. There were no bacteria in these sections. After an acute exacerbation in October, 1928 he was given a vaccine of three type strains of streptococcus and a staphylococcus from his antrum without relief from the recurrences of infection, filtrates were administered from this time on. Tests of his serum at the time of the recurrences of the facial infection showed antitoxins for both staphylococcus and streptococcus. Early in 1929 a double sinusotomy was done and the roots of several teeth were extracted. Inoculations with streptococcus and staphylococcus filtrates were then continued until March, 1932 without subsequent recurrences of infection. The inflammation and edema had then subsided leaving the face normal except for residual fibrosis (fig 2). During his immunization, attacks were provoked at times by the administration of filtrate. The edema and swelling were increased after these attacks, until the amount of filtrate administered was decreased. Finally the patient was able to tolerate large doses of undiluted filtrate.

upper lip were firm, swollen and inflamed. According to the history, the attacks of inflammation had begun on the left cheek, and then occurred alternately on the two sides until the edema was permanent, after this, the two cheeks were affected simultaneously. When these attacks occurred, the swelling increased gradually for two or three days before reaching a maximum, occasionally papules appeared on the cheeks, and then the inflammation slowly subsided. Material aspirated from the skin showed staphylococci but no streptococci, and none were found in cultures of the nose and throat. The tonsils had been removed. The teeth and gums were not infected. Investigation of the nose showed a purulent infection of the antrums and ethmoids, which were drained and irrigated for six months when a left maxillary sinusotomy was considered necessary. Cultures of the antrum yielded *Staphylococcus aureus*. Continued antral irrigations and the administration of an autogenous vaccine of this bacterium failed to reduce noticeably the swelling of the face or to prevent intermittent acute inflammation.

In December, 1929, the skin of the forearm was tested with filtrates and nucleoproteins of *Staphylococcus aureus* and hemolytic streptococcus. The staphylococcus filtrate, both with and without toxin, and the nucleoprotein of this coccus caused local erythema, but streptococcus products gave no reaction. Following these tests the patient was given subcutaneous doses of staphylococcus toxic filtrate during the winters of 1929, 1930, 1931 and 1932. Local reactions similar to those observed in the previous case occurred during these inoculations. After the inoculations were begun the edema began to subside and at the present time is scarcely noticeable. Aside from one mild attack in May, 1932, she has had no recurrent infections. During the winter of 1932-1933, filtrates of staphylococcus in which the toxin had been destroyed by aging were used, instead of fresh toxic preparations. Focal reactions were as definite and as severe with these filtrates as with those containing toxin. Equivalent amounts of streptococcus filtrate failed to evoke swelling and inflammation of the face.

CASE 4—M S, a man, aged 34, had an attack of facial erysipelas in January, 1929. Ushered in with a chill, fever, malaise and vomiting, the swelling started at the angle of the mouth and spread over the face, with subsequent closure of the eyes. Attacks of this type, typically erysipelatous, continued at weekly intervals, with some subsidence of the constitutional but not of the local reaction, until the patient was seen in the clinic in March. All the attacks had followed the same course, extending from the lip over the left side of the face. The patient was first observed during the resolution of a recent attack from which the lips, the left cheek and eyelids, and the nose were still inflamed, edematous and vesiculated. The inside of the mouth was inflamed, as well as the skin of the face. Numerous elevated bluish white papules were found on the mucous membrane of the upper lip and the cheeks. Cultures of these papules showed both monilia and hemolytic streptococcus. The left antrum appeared to be infected, but the cultures showed no bacteria.

The skin of the forearm was tested and found sensitive to the filtrates of two of three strains of streptococcus from erysipelas and to streptococcus nucleoprotein, confirming the impression that the infection was of the streptococcal variety. The mixed filtrates of these three strains were administered in increasing doses during April, May, June and July. Attacks occurred at weekly intervals until June and then ceased. A mild attack followed a provocative injection of filtrate in August, a mild spontaneous attack occurred in November and a severe exacerbation in the early summer of 1931. Following this last attack, filtrates were administered by the patient's physician for six months. Attempts to eliminate the monilial infection entirely were futile. In July, 1932, he was admitted to the

hospital for the study of a pentosuria. He had not had attacks for nine months. Although the face was not edematous, the upper lip, the left cheek and the lower left eyelid were slightly fibrosed.

CASE 5—E M, a girl, aged 17, first noticed irregular nodular swelling of the buccal mucous membrane and of the cheeks. These mild inflammatory attacks occurred at irregular intervals, but a typical acute attack of erysipelas six months after the onset was followed by similar attacks at intervals of about eight weeks. In 1919, three years after the onset of the infection, the left antrum was irrigated and a strip of tissue was removed from the upper lip, which had become hypertrophied and fibrotic. Short periods of freedom from attacks were observed following this operation, following childbirth in 1922, and later, subsequent to a second period of antral irrigations and the administration of a vaccine of hemolytic streptococcus from cultures yielded by material from this sinus.

The patient was first seen in January, 1927. The upper lip was slightly edematous and fibrotic, and the left side of the face was swollen but without marked deformity. The buccal mucous membrane was roughened with acuminate eroded papules. Cultures of the throat and of the buccal membrane

Fig 3—Patient 2, Feb 8 1930, previous to treatment.

Fig 4—Patient 2 Nov 11, 1932, subsequent to desensitization with staphylococcus filtrates.

yielded a hemolytic streptococcus and a diphtheroid. Since one period of freedom from attacks had followed the administration of streptococcus vaccine and the attacks at this time were mild and occurring only at intervals of from four to six months a vaccine prepared with three erysipelatous strains was administered at intervals of a month. Recurrences continued at irregular intervals under this treatment. In August, 1932, a course of filtrate of the same three strains was given to check the frequent occurrence of nodular swelling of the cheeks similar to the lesions observed prior to the onset of erysipelas. The sinuses, tonsils and teeth were found free from infection at this time. The swelling ceased following these inoculations. Cutaneous tests with toxic filtrates of the three strains of streptococcus from erysipelas, toxic filtrates of staphylococcus and nucleoproteins of these bacteria were negative on several occasions. The blood serum of the patient, obtained during an acute attack, neutralized the toxin of *Streptococcus hemolyticus* and *Staphylococcus aureus*.

COMMENT

Birkhaug believed that the immunity developing in the course of an attack of erysipelas was antitoxic but, after Francis suggested the possibility that the patho-

genesis and the recovery from an attack might be of an allergic nature¹¹ admitted the probability of a hypersensitive element in the recurrent infections¹². In addition to the observations leading Francis to advocate this theory, clinical observations by Amoss and Birkhaug have further substantiated this hypothesis. Redness and inflammation occurring at the site of a recurrent erysipelas immediately following inoculations with streptococcus filtrate have been reported by both authors.

These focal reactions are analogous to the reactions in tuberculous patients at the site of infection after the injection of tuberculin and indicate a hypersensitization of the tissues that react to bacterial products injected. In one instance, in a child with staphylococcal infection, Amoss observed reactions of this variety following inoculations with toxic staphylococcus filtrate. I have observed these reactions in the patients with edema of the face with both streptococcus and staphylococcus filtrates. In each instance in which the reactions occurred, inoculations with other filtrates than those corresponding to the bacteria recovered from the infected tissues have failed to evoke a focal response, thus proving the specificity of the focal response. These specific focal reactions, together with the course of the patients during inoculation, are both evidence of extreme hypersensitization to bacterial products. The fact that the reactions were caused by critical doses of filtrate, and subsequently, after several such doses were administered, much larger doses were tolerated without the least reaction but with subsidence of the inflammation, suggests desensitization of the edematous tissues by the series of inoculations. The presence of antitoxins for streptococcus and staphylococcus in the blood of these patients and the negative cutaneous reactions to toxic filtrates prove an existing immunity to the toxins of these bacteria and further substantiate my belief that the treatment desensitized rather than immunized. As might be anticipated, one course of inoculations has been insufficient to reduce the edema and inflammation and prevent recurrences. Exacerbations have occurred in the intervals between the series. But after several series extended over a period of three or four years, complete and permanent desensitization has apparently been accomplished.

Filtrates of staphylococcus and streptococcus from cultures grown four days contain toxic substances and disintegration products from the bacterial cell. When the toxic fraction in the filtrates is destroyed by heat, oxidation or aging, these filtrates are still capable of causing erythematous tuberculin-like reactions if injected intracutaneously in certain patients and in previously sensitized animals. These reactions, I have found, correspond to reactions obtained with the purified nucleoprotein derived from the cell bodies. The last series of inoculations given these patients was with filtrates devoid of the toxic fractions, yet the focal responses evoked, and the courses of the patients during these series, were similar to those observed with the toxic filtrates. One of the staphylococcal infections reacted to 0.005 mg of purified nucleoprotein. While the possibility that the edematous tissues might be hypersensitive to toxin even in the presence of antitoxic immunity cannot be completely excluded these reactions with detoxicated filtrate and the nucleoprotein

of the bacteria lead me to believe that hypersensitization to material derived from the disintegration of the cell bodies is the principal factor in the pathogenesis of the edema.

ROENTGEN VISUALIZATION OF LIVER AND SPLEEN WITH THORIUM DIOXIDE SOL

WITH PARTICULAR REFERENCE TO THE PREOPERATIVE
DIAGNOSIS OF CARCINOMATOUS
METASTASES TO THE LIVER

LESTER G. ERICKSEN, M.D.

DUBUQUE, IOWA

AND

LEO G. RIGLER, M.D.

MINNEAPOLIS

Since Radt's¹ original publication in 1929 of his work on visualization of the liver and spleen with a colloidal suspension of thorium dioxide (now marketed under the trade name of Thorotrast) injected intravenously, numerous reports have been published in both the American and the foreign literature on almost every phase of this problem. Until Radt's work, methods of examination of the liver and spleen were limited to very gross means of determining its size through indirect methods such as palpation, roentgen examination of the colon, and pneumoperitoneum. There were no means of demonstrating structural changes within these organs. The spleen and liver had been visualized in animals while other problems were being worked on, but with lethal results.² Radt, first working with animals and later with human beings, was able to visualize the liver and spleen and demonstrate gross changes very beautifully with a fine colloidal suspension of thorium dioxide. The colloidal particles of radiopaque thorium dioxide are phagocytosed by the reticulo-endothelial cells of the liver and spleen, thus casting a shadow of these organs on the x-ray film. Later workers have confirmed Radt's work and also broadened its scope, so that now there are numerous publications dealing not only with the experimental side but also with its clinical application.³ The latter consist for the most part of case reports. There has been no report of the results of the use of this procedure as a routine examination preoperatively in cases of malignancy, particularly those of

the gastro-intestinal tract. This paper will concern itself primarily with the utility of this procedure.

Work on this problem was begun immediately following publication of Radt's original report and has been carried on continuously since, first with animals and later in clinical cases. Up to this writing we have used the method in eighty-two cases of various types with very gratifying results. We have found the clinical application of it to be surprisingly broad and useful. At the present time it is being used as a routine procedure, preoperatively, in all cases of malignancy of the gastro-intestinal tract to rule out metastases to the liver which are known to occur so early in cancer of the stomach and bowel. We have also found it very useful in other types of metastases, cirrhosis of the liver, primary tumors, abscesses of the liver, differentiation of abdominal masses and the like. The average number of patients receiving thorium dioxide sol at this writing is about four a week.

The experimental phases of the problem have been well worked out by many investigators and will not be discussed in this paper.⁴ Since the reticulo-endothelial system is the fundamental basis of the procedure, however, it will be described briefly. The mesenchyme of the embryo is the origin of the so-called reticulo-endothelial system. A certain number of the mesenchyme cells retain their embryonic developmental potentialities and become converted into tissue histiocytes, belonging to one of two types, called respectively the free and the fixed histiocytes. The free histiocytes, wandering cells, or macrophages, have phagocytic prop-

scattered system of specialized endothelial cells is sometimes called the reticulo-endothelial system. Maximow⁵ objects to this name, however, for the reason that it refers to only one representative of the system, the reticular cell, and secondly that it creates the incorrect impression that the endothelium of the common blood vessels also belongs to this system. He prefers the term histiocytic system.

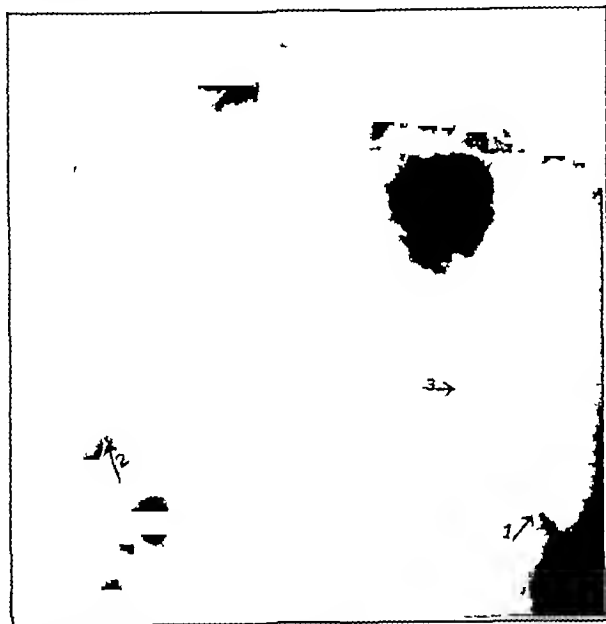

Fig 2—Cirrhosis of liver. Same case as figure 1, showing relative size of spleen to liver. Arrows 1 and 3 point to border of spleen which is markedly enlarged. Arrow 2 points to lower border of liver.

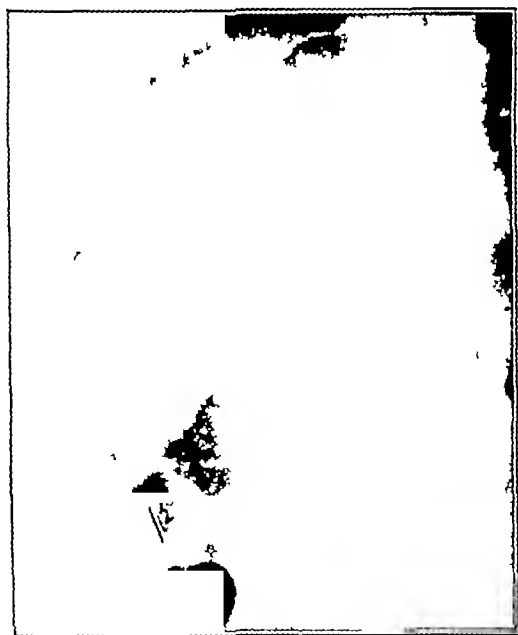

Fig 1—Cirrhosis of liver moderately advanced. Local film for detail of fine mottling of liver, arrow points to the lower border of the liver.

erties and are to be found in the connective tissue. The fixed histiocytes, or resting wandering cells, are to be found in large numbers in the serous membranes, especially in the omentum and also as histiocytes that have taken up the position of an endothelial lining. This

These cells are found scattered widely throughout the body but are more concentrated in the liver and spleen, where they line the venous sinuses of the two organs. In the liver the cells are known as the Kupffer or stellate cells. The lymph nodes, bone marrow, lungs, kidneys and suprarenals are also well supplied with histiocytic cells. This widely disseminated system comprises cells of very differing function, shape and appearance, but they all possess in common the property of ingesting foreign particles of varying grades of size. It was on this principle that Radt developed his method of visualizing the liver and spleen roentgenologically. The colloidal particles of thorium dioxide, which are opaque to x-rays, are carried through the venous sinuses of the liver and spleen and are phagocytized by the histiocytic cells. How long the thorium particles remain here has not as yet been accurately determined. Elimination is very slow, however, and probably occurs through the intestine and the lungs. Leipert⁴ recovered about 70 per cent of the thorium from the liver, spleen and kidneys of a rabbit injected three months before. We have recently undertaken the study of the effect of various drugs in hastening the elimination.

There have been some scattered reports in the literature of damaging effects on the liver and spleen,⁶ disturbances of blood counts, and the like, but the majority

of these reports show that it has been necessary to give excessive doses to accomplish these results. Most investigators have yet to discover any damaging effects when used in the doses necessary for diagnostic visualization.⁷ It has not been definitely proved, however, that this procedure is entirely harmless. An analysis that calls attention to the potential dangers of the use of thorium

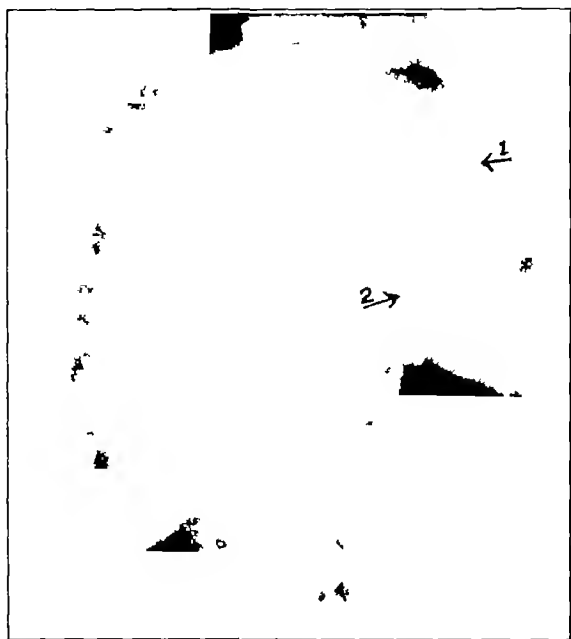

Fig 3—Extensive sarcoma of liver in child of 18 months. Arrow 1 points to largest tumor mass; arrow 2 points to medial border of spleen. Only small areas of normal liver remain to show opacity of thorium.

dioxide sol is given in the report of the Council on Pharmacy and Chemistry.⁸ As is pointed out in this article, the greatest danger probably lies in the radioactivity of the thorium. It has been shown that the immediate effects from the radioactivity are minimal, and no harmful effects have been observed locally or generally.⁹ Thorium resembles radium, however, in that it breaks down into the subproducts of mesothorium, radiothorium, thorium X, thorium emanation, thorium A, thorium B and thorium C, which, as they are formed, in turn give off alpha, beta and gamma rays. The alpha rays are the only ones that may concern us. When the radioactivity of thorium reaches its minimal level, it then takes about seven years for thorium and its subproducts to reach approximately six tenths of its potential radioactivity.¹⁰ If the radioactivity of thorium is taken to be 1 originally, then after about

seven years it will be approximately 15. With the maximum dose of 75 cc of thorium dioxide sol, one would get an accumulated alpha ray activity to from 15 to 3 micrograms of radium, should no elimination take place.

Although the limit of tolerance for the average person was formerly thought to be about 10 micrograms of radium, bone and tooth changes have been observed in the bodies of radium workers that contained the equivalent of from 2 to 4 micrograms of radium.⁸ Therein lies the potential element of danger in its use. Whether this effect of the radioactivity is enough to do the patient any harm is very doubtful, since elimination is taking place constantly. Because of the uncertainty of the speed of elimination, it would be difficult to measure the exact effect of this radiation on the body. As already stated, Leipert has demonstrated 30 per cent elimination from the liver, spleen and kidneys of a rabbit at the end of three months. If this ratio of elimination should continue, one would have but little to fear from delayed radioactivity. The best check on this will probably be the final observation on the patient. Thus far, no harmful effects whatever have been observed by Radt⁷ over a period of three and a half years during which animals were followed and two years during which the human cases have been followed. In view of what has been stated, this period of observation is still too short to demonstrate the harmlessness of the procedure. Deleterious effects from the delayed radioactivity might not begin for four or five years after the administration of the material and might conceivably be delayed for as long as nine or ten years. With these facts in mind, the utilization of this method should be cautiously restricted until sufficient time has elapsed to permit a final conclusion as to the actual dangers involved. It is fortunate that the cases in which this diagnostic aid is of most value are those in which the eventual mortality rate is very high, whether the procedure is used or not. Also, the age of these patients is usually advanced. We believe it is wise, until time has eliminated the possibilities of danger from latent radioactivity, to confine it to this group. In other types of cases the dose we have used for outlining the liver and spleen is from one third to one fourth the average dose, and we do not believe this could cause any harm.

¹⁰ If the radioactivity of freshly isolated thorium is taken as 100 per cent (considering only the emission of alpha particles) in from four to five years it will decrease to about 50 per cent of the initial level. This is due to the fact that radiothorium, one of the disintegration products of mesothorium, is chemically inseparable from thorium. During the time the radiothorium is disintegrating the concentration of mesothorium (which does not emit alpha particles) is constantly increasing. At the end of the four or five year period enough radiothorium is regenerated from the mesothorium again to increase the emission of alpha particles in seven more years about one third of the difference is made up in ten years about one half. In order to have thorium dioxide sol at its minimum level of alpha radioactivity it would have to be made from thorium aged from four to five years. The Council on Pharmacy and Chemistry has had no evidence presented that Thorotrast is made from thorium so aged. It seems fair to assume then that Thorotrast as it appears on the market is near its maximum alpha radioactivity. This activity would then follow the curve just elucidated.

One of the functions of the reticulo-endothelial system is to protect the body against infections. The question has been raised as to whether or not the ingestion of the thorium particles by the reticulo-endothelial cells would reduce the defense of the body to these infections. Much has been written with much disagreement on the question of the so-called blocking of this system with colloidal dyes. Some investigators

have found that the animal's resistance was definitely reduced while others have found that it was stimulated. It is a common belief now that since these histiocytic cells are so widely distributed throughout the body it is almost impossible to obstruct the system. Furthermore, microscopic sections of the liver and spleen show that only a small percentage of these cells ingest the

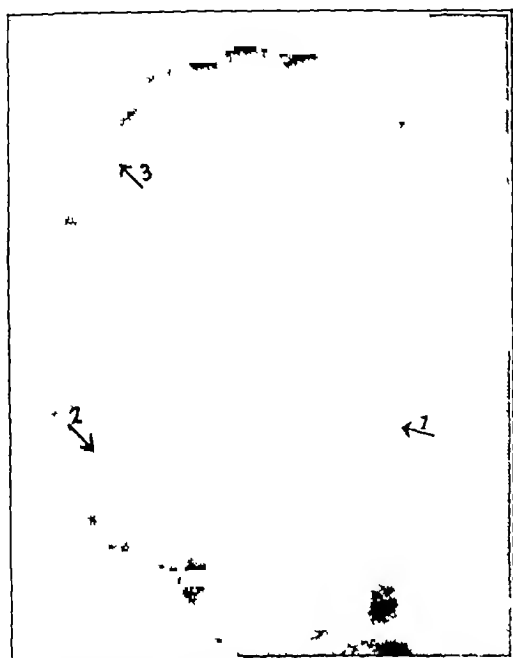

Fig 5—Carcinoma of stomach with extensive metastases to liver with mottled moth eaten appearance of liver. More definite areas of metastasis are indicated by arrows 2 and 3. Arrow 1 points to liver edge.

thorium, so that this function of the reticulo-endothelial system is very slightly interfered with. In twelve cases of our series, postmortem examination was done at some time after the injection. In all these, careful sections of the liver and spleen were made. The thorium dioxide suspension was detected in the form of refractile bodies in some of the histiocytic cells. A great many cells did not show any of the material and there was no histologic evidence whatever to indicate any cell damage resulting from the foreign body particles. This is the rule, we believe, when amounts not exceeding 0.8 cc of thorium dioxide sol per kilogram of body weight is used. Animals have been exposed to infection and it has been found that those who had been injected with colloidal suspension of thorium dioxide did not withstand infection quite as well as the control animals, however about five times the adult diagnostic dose was used.¹¹ We, as well as others, have been unable to detect any reduction in the defensive powers of the patient to infection. Dr O H Wangenstein, chief of the department of surgery at the University of Minnesota Medical School, can detect no difference in the postoperative convalescence of a patient who has had thorium dioxide sol and one who has not.¹²

Another point that might be considered an objection to the use of this medium is the length of time it remains within the body. So far, no observations have been made of harmful effects of this delayed elimina-

tion. We have found that this has one advantage. A patient who has been given the preparation may show no evidence of metastasis to the liver on the first examination, with the subsequent development of a metastasis, the roentgen studies may be obtained without further injection. We have had one such patient. It has been quite definitely proved by a number of workers that there is no other possible harm from the use of the colloidal suspension of thorium dioxide.¹³

Contraindications to the use of this preparation have not been well worked out, and those which have been listed are based more on theoretical than on practical grounds. Among those mentioned are conditions wherein the liver function is markedly interfered with, such as liver atrophy, pronounced icterus and far advanced cirrhosis. Extreme enlargements of the spleen and liver have been listed perhaps because of the case of splenomegaly, reported by Buengeler and Krautwig,¹⁴ which ruptured following the injection of thorium dioxide sol. The various syndromes involving lipid dysfunction, Schuller-Christian, Gaucher and Niemann-Pick disease are reported as contraindications on the assumption that the reticulo-endothelial cells have ingested large amounts of fat and are already more or less occluded. It is said that patients who have high temperatures and are extremely toxic are poor risks, but in our experience this is no more true than with other procedures of a similar nature. We have observed no contraindications and have been unable to detect any harm, either experimentally or clinically, with but one exception. This patient was a woman with a far

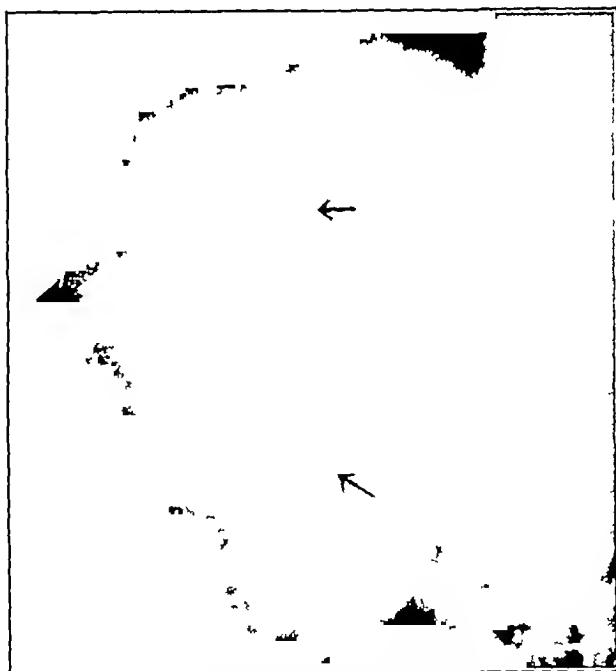

Fig 6—Carcinoma of rectum with Metastases to liver. Large defects in the liver shadow indicate the presence of the metastatic nodules (arrows).

advanced cancer of the stomach. About three hours following the first intravenous injection of 25 cc of thorium dioxide sol, she began to have hematemesis, hemoptysis and hematuria. It was necessary to give

the patient a transfusion, and she recovered. Previous to this experience we had used the German preparation, but the material used in this case was the first shipment we had received of the product made in this country. Our interpretation of the cause of this reaction was that the size of the colloidal particle of thorium dioxide was too large and the reaction was due entirely to multiple emboli. Following a change in the p_H of the suspension, we have had no more difficulty. In some of the original animal experiments, this difficulty was encountered, the animals dying of cerebral emboli. It is important that the size of the colloidal particle be very small to avoid this.

This procedure may be used to advantage in a number of conditions in which hitherto we have been severely handicapped in making an accurate diagnosis. Perhaps foremost in value is its application to the preoperative diagnosis of metastasis to the liver. Until Radt's contribution, many an abdomen was opened only to be

other primary malignancies when indicated and has proved valuable in preventing needless surgery in many cases.

In almost the same category as the metastatic tumors are the primary tumors (fig 3), cysts and abscesses of the liver and spleen. Although these conditions are rather sporadic in hospital practice, it is nevertheless very helpful to be able to diagnose a case when it is presented. Several case reports have now appeared in the literature on hepatosplenography wherein a diagnosis has been made by this means.

Often a controversy arises concerning the origin of an abdominal mass. The liver or spleen can easily be visualized by a small dose of thorium dioxide sol and diagnosis thus clarified to that extent. Determination of the size of these organs comes in this same field (fig 2). We have been able to demonstrate enlargement of the liver or spleen several times when it was not apparent clinically.

To the clinician, cirrhosis of the liver is one of the most difficult diseases to diagnose in the early stages. It is in the early stages that visualization of the liver and spleen with thorium dioxide is of the greatest help. In place of the homogeneous shadow normally seen on the roentgenogram, one sees a very fine nodular mottling (fig 1). The normal liver tissue capable of taking up the thorium is separated in a netlike manner by the cirrhotic tissue that has replaced it. As the disease progresses to its later stages, this mottling may be lost as more of the normal liver tissue has been replaced, and a shadow of much decreased density appears until finally no shadow is apparent at all. Another helpful point in this condition is the relative increase in the size of the spleen to the liver (fig 2). We have had three cases of liver cirrhosis and they have all shown this picture constantly. We have studied a few cases of leukemia and Hodgkin's disease but, since there is usually no difficulty in the diagnosis of these conditions clinically, we can see no particular value in its use here. The lymph nodes are not visualized following intravenous injection of thorium dioxide sol unless the liver and spleen are practically filled by a very large dose or many of the normal liver cells are replaced by pathologic tissue which will not take up the thorium particles. A case in point is illustrated in figure 3. A baby, aged 18 months, had a large primary sarcoma of the liver with very little normal liver tissue remaining. The anterior and posterior chain of cervical nodes were well demonstrated (fig 4).

As we have gained experience in the use of this procedure, our technic of injection has been modified from that originally described by Radt,¹ Kadrnka,² and other early workers. They advised that the 25 per cent suspension of thorium dioxide (Thorotrast) should be diluted 1 to 10 in 5 per cent dextrose and slowly injected intravenously in graduated doses, starting with as small a dose as 0.1 Gm per kilogram of body weight. If the patient experienced no reaction, this was increased slowly until a total of 0.8 Gm per kilogram of body weight had been given. Our first few patients were injected in this way. Animal experimental work showed, however, that the dilution was unnecessary. A total dose of 0.8 cc of thorium dioxide sol per kilogram of body weight gives a very diagnostic shadow of liver and spleen when detail is wanted. This is given in three equal doses on successive days. We have never found it necessary to give more than this dosage. Several times we have visualized tissue

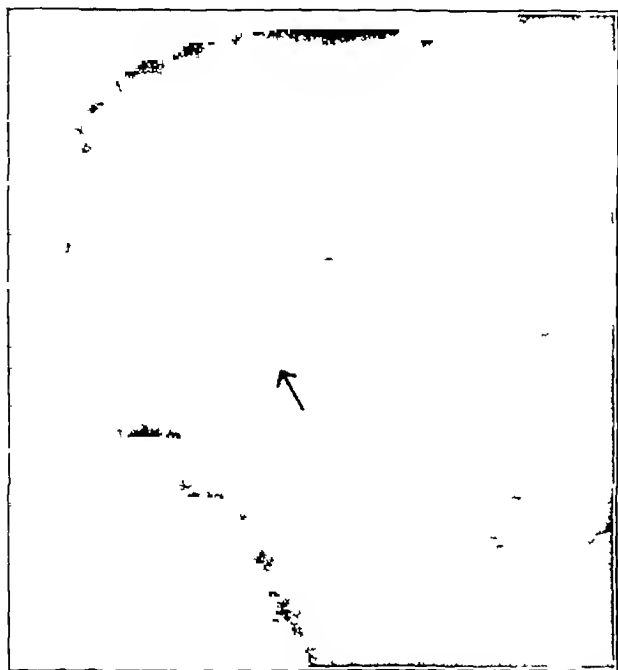

Fig 7.—Normal liver as visualized by thorium dioxide sol. Gas in hepatic flexure of colon overlying liver care must be exercised to differentiate this from the defect of metastasis.

closed again without further surgery because of metastasis to the liver. It is a well known fact that carcinoma of the stomach metastasizes to the liver at an early stage (fig 5). Too often a malignant growth of the stomach which is easily resectable from the standpoint of the local lesion will prove inoperable because of liver metastasis when the abdomen is opened. The operative treatment of carcinoma of the rectum is a very formidable undertaking. How often has a patient uselessly been put through this distressing experience only to die a short time later of metastasis to the liver (fig 6)? Nevertheless, no surgeon wishes to deny a patient the benefit of an operation that may cure him of a disease the result of which is otherwise uniformly fatal. It is little wonder, then, that this new diagnostic aid has been so welcome. In the department of surgery at the University Hospital, University of Minnesota, this procedure is now a routine in all preoperative cases of malignancy of the gastro-intestinal tract and in

detail very well with 50 cc. It is always advisable to give the smallest dose possible for a diagnosis. If it is merely a question of the size of the liver or spleen or the differential diagnosis of an abdominal mass, one ampule (25 cc.) is sufficient. The speed of injection makes little difference, but it is important to warm the preparation to body temperature before giving it.

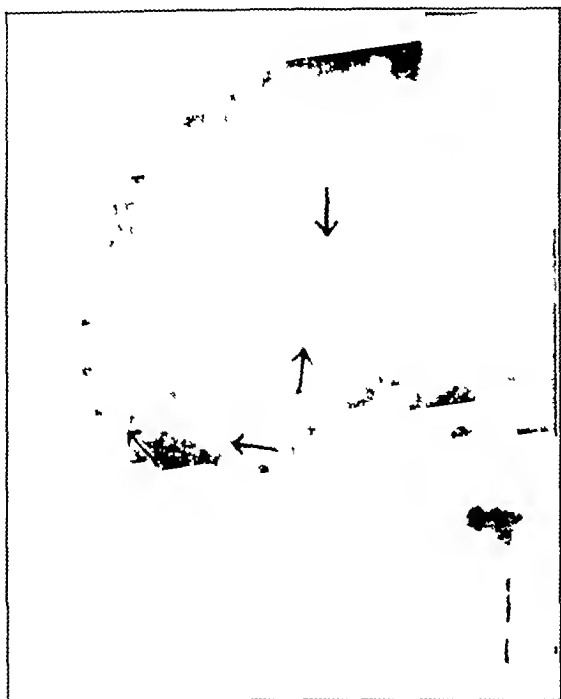

Fig 8—Normal liver as visualized by thorium dioxide sol. Rounded area of rarefaction in medial portion is constantly seen in region of gallbladder fossa and striations which are due to venous channels (arrows).

We have observed only the one severe reaction in spite of the fact that we have carried out the procedure on some patients who were in very poor condition.

The films should not be taken sooner than twenty-four hours following the last injection and they are better at forty-eight hours. It has been well shown that there are free thorium particles in the venous sinuses of the spleen even two weeks after the injection, indicating the slowness with which the particles are taken up from the blood stream¹⁵. Thus, at forty-eight hours, a better shadow will be seen than at twenty-four hours. A 14 by 17 inch film is taken of the abdomen on the Potter-Bucky diaphragm with the patient prone. A relatively heavier exposure is given here than with the routine abdomen film. This large film will give the relative relationship and size of the liver and spleen. If detail is desired, a second film of 10 by 12 inch size is taken, centering over the lobes of the liver or spleen, the Potter-Bucky diaphragm and a large diaphragm opening being used. A third film is then taken, the same factors being used with the exception that a slightly heavier exposure is given. The latter film will be somewhat darker than the former. The lighter film will show metastatic areas in the thinner portions of the liver, while the darker brings out areas of rarefaction in the thicker portions.

Interpretation of the films in the field of malignancy requires much experience but may become very accurate. Metastatic areas, abscesses, cysts or other tumors

will all show as areas of rarefaction in the liver, giving it a mottled appearance (figs 5 and 6). If these areas are numerous, the problem is very simple. It is not possible to differentiate from a roentgenologic point of view between abscesses in the liver and metastases. Both will appear as ragged areas of rarefaction, while cysts have a sharper, more circumscribed border. One must, however, be very careful of shadows cast by overlying gas in the bowel (fig 7). Should there be bowel shadows overlying the liver, which are confusing, a cleansing enema should be given. Occasionally gas in the duodenum will be confusing. This, however, will not be constant on successive examinations. The constancy of the rarefied areas as to location and size in the series of films taken is also very helpful. Occasionally the vascular channels of the liver stand out exceptionally well (fig 8). These, however, have a radiating character and are linear and sharply defined. An area of rarefaction is usually seen in the gallbladder fossa, probably owing to the large ducts in this region (fig 9). We have observed a case of considerable interest in this connection. A woman had been operated on for cholecystitis three times by competent surgeons, and no gallbladder had been found. An examination with thorium dioxide sol revealed a large defect in the region of the gallbladder fossa which we interpreted as being produced by an intrahepatic gallbladder. This

Fig 9—Normal liver as visualized by thorium dioxide sol. Normal defects in region of gallbladder fossa are caused by larger bile ducts (arrows).

fossa is always sharply defined, always in the same location and causes little trouble when one gains experience in interpreting the films. To date, we have been checked either by operation or by postmortem examination on twenty-two diagnoses, and in twenty-one of these the diagnosis given previous to the operation proved correct. Fourteen cases were reported as presenting no malignant metastasis, while metastases were

present in eight. Twelve were checked by autopsy and ten by operation. The one case in error was in a man, aged 48, with a carcinoma of the stomach. He was reported as having no carcinomatous metastasis to the liver. A resection was done and the patient died the ninth day after operation of peritonitis from a leak at the anastomosis. At autopsy he had one small metastatic area about 1 cm in diameter. On reviewing the original films, this was easily recognized.

It is preferable to make an error on the negative side, however, than on the positive side. Occasionally we have been in doubt in a case that showed possibly one small questionable area of defect in the liver. Our advice in such a case has been to give the patient the benefit of the doubt and do a resection if nothing is found on exploration, since the mortality would be 100 per cent without the operation. Until, through much experience, we feel entirely confident in our diagnostic ability, we believe this to be the best attitude to take. Up to the present time, we have used this procedure in eighty-two cases of various types, distributed according to the accompanying table.

Distribution of Various Types of Disease

Disease	No of Cases	Disease	No of Cases
Carcinoma of stomach		Carcinoma of lung	
Negative diagnosis	20	Negative diagnosis	1
Positive diagnosis	10	Cirrhosis of liver	
Carcinoma of colon		Positive diagnosis	3
Negative diagnosis	3	Actinomycosis	
Carcinoma of rectum		Positive diagnosis	1
Negative diagnosis	5	Intrahepatic gallbladder	
Positive diagnosis	0	Positive diagnosis	1
Carcinoma of breast		Hodgkin's disease	
Negative diagnosis	3	Negative diagnosis	2
Positive diagnosis	3	Positive diagnosis	3
Carcinoma of ovary		Size of liver and spleen	0
Negative diagnosis	1	Differentiation of abdominal masses	2
Primary malignancy of liver		Leukemia	3
Positive diagnosis	2	Pernicious anemia	1
Malignancy primary unknown		Polycythemia vera	1
Negative diagnosis	1	Subdiaphragmatic abscess	1
Positive diagnosis	2		
Melanoma			
Negative diagnosis	1		

SUMMARY

1 Hepatosplenography is of value as a routine examination preoperatively in cases of malignancy.

2 To date, this procedure has been used in eighty-two clinical cases of various types without apparent harm and with very gratifying results.

3 It has been found to be of great value in gastrointestinal malignant growths preoperatively.

4 In the interpretation of films, when in doubt a negative diagnosis is made.

5 Certain phases of this procedure which hitherto have not been emphasized, are:

(a) The advantage of delayed elimination in the follow-up examination for the demonstration of the development of metastases.

(b) The danger of delayed radioactivity of thorium after several years.

(c) Its particular value in preventing needless surgery in cases of malignant growths of the gastrointestinal tract.

(d) The fact that films should not be taken sooner than twenty-four hours following the last injection.

(e) The observation of an area of rarefaction constantly seen in the region of the gallbladder fossa.

(f) The unusual accuracy of the procedure.

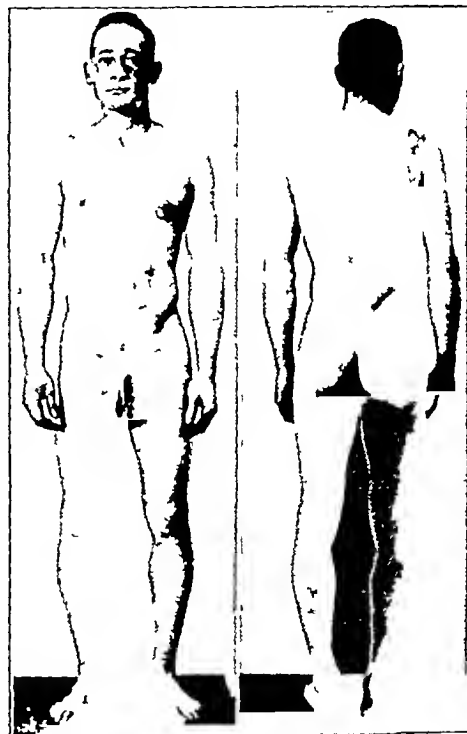

Clinical Notes, Suggestions and New Instruments

TOTAL LOSS OF PIGMENT IN A NEGRO (ACQUIRED FORM)

ELMORE B. TAUBER, M.D. AND RAYMOND G. SENOUR, M.D. CINCINNATI

Achromoderma in the Negro may be classified in two forms, the congenital and the acquired. Reports of cases of the congenital type are numerous. Musser, in 1924, traced a family tree of three generations of Negroes and showed recessive characteristics in albinos. The literature since then has been voluminous but has no bearing on our particular case.

The second, or acquired, form of achromoderma is extremely rare. Only one other case has been reported up to this time. This report was published in 1931, by Dr. Lewis A. Golden¹ of Boston. A resume of this Negro's condition appeared in the *Boston Medical and Surgical Review* on July 26, 1917, the case

Appearance of patient after pigment returned in a few areas following exposure to ultraviolet rays.

having been shown by the late Dr. Thorndyke. Apparently, our case is the second of its kind.

REPORT OF CASE

J. W., a Negro, aged 32, had a rash seventeen years ago, which covered the entire body. He attributed it to the heat. Following the disappearance of the rash, areas of depigmentation made their appearance, first on the arms and then gradually over the entire body.

In 1917, the patient enlisted in the army, and at that time had a total loss of pigment. A Wassermann test of the blood was negative. In 1919, a penile lesion developed, for which he was given several intravenous injections of neoarsphenamine. These had no effect on the depigmentation.

During the summer of 1930, he exposed himself daily to sunlight and ultraviolet rays, and a few isolated spots of pigment reappeared on the face, neck and shoulders. He presented himself at our clinic on Sept. 24, 1930. The Wassermann test

From the Department of Dermatology, Cincinnati General Hospital and the Department of Medicine, University of Cincinnati.
¹ Golden, L. A. Complete Loss of Pigment in the Skin of a Negro, *Arch. Dermat. & Syph.* 24: 1069 (Dec.) 1931.

was positive. The blood picture was normal, urinalysis gave negative results, and the blood pressure was 125 systolic and 80 diastolic.

It is an interesting fact that this patient was without pigment in the skin from 1917 to 1930.

SUMMARY AND CONCLUSIONS

1 The second case of complete leukoderma in a Negro is recorded.

2 In both Dr. Golden's case and our own trauma was the exciting cause followed by a rapid depigmentation.

3 The return of a few pigmented spots after exposure to actinic rays shows definitely that the cells are still capable of producing pigment if the proper stimulation is given them even after long periods of quiescence.

4 Syphilis had no influence on the leukoderma.

THE USE AND VALUE OF GOLD RADON SEEDS

IRA I. KAPLAN, M.D., NEW YORK

Director, Division of Cancer, Department of Hospitals; Visiting Radiation Therapist, Bellevue Hospital; Clinical Professor of Surgery, University and Bellevue Hospital Medical College.

As far as present knowledge goes the only therapeutic agents of value in the treatment of malignant conditions are surgery and radiation or a combination of the two.

In irradiation, the element radium is of the greatest importance. Its cost, however, being very high, a less expensive agent but one equally effective was sought, one whose use could be made more general by reason of its lower cost. Such an agent, fortunately, was found with the progress in the study of radium. It was noted that as radium decayed it emitted a gas possessing the same physical and biologic characteristics it had itself. This gas, designated as radon, is short lived, however, lasting no longer than about a month.

Despite this drawback radon came as a powerful aid in the field of radiation therapy in the treatment of neoplastic diseases. Duane in 1914 found that this gaseous radioactive substance could be piped into small glass capsules by which tissues could be irradiated both intratumorally and from the surface. This discovery opened up a new field in cancer treatment and many favorable results followed irradiation by these radon tubules.

It was noticed, however, that in many cases following treatment with these tubules, severe necrosis of both the neoplastic and surrounding normal tissues occurred. Accordingly a careful study was made of the rays emitted from these glass tubules and it was found that while the glass capsules had absorbed the alpha radon rays, the caustic beta and penetrating gamma rays were scarcely affected. Because the beta rays were known to be caustic and destructive in character their elimination in the treatment was necessary in order to avoid burns, except in some minor instances.

Experimental studies have shown that beta rays are absorbed by certain metals, the thicker the metal the greater the absorption. These metals are called filters. In order to filter out the caustic rays in the glass tubules the latter were surrounded by metal, but because the early filter material used was brass or lead the tubules thus covered were rather bulky and quite awkward in use. To overcome this Fiella in 1924 suggested making radon tubules directly from finely drawn gold tubing equal in diameter to the glass tubing theretofore used, but the gold being of 0.3 mm wall thickness, would filter out 98 per cent of the caustic rays rendering unnecessary any bulky external filtration. As these tubules were rather small, they were commonly called "seeds."

In 1924 I began constructing the seeds of platinum with a thread attached to one pole for withdrawal after they had served their purpose in the tissues being treated. However while in some instances the removable radon tubules or seeds might be considered to possess an advantage over the nonremovable type, my experience in the use of both types of applicators in a large group of cases over a long period of time has led me to conclude that the gold seed is of equal value to the removable type and equally applicable in any condition for which this method of therapy is indicated.

Because of some adverse criticism of gold seed radon tubules and some statements reflecting on their leak-proof character I was requested by the New York City Department of Hos-

pitals which purchases large quantities of these seeds, to test the commercial product for content stability and leak-proofness. The tests were made in our physical laboratory as follows:

"Samples of gold seeds" bought in the open market and from the Department of Hospitals were measured by ionometric gamma ray comparisons with a known radium standard.

The seeds were placed in a high pressure sterilizer and left there for half an hour with a steam pressure of 20 pounds. After sterilization the "seeds" were aged three hours and then their intensities were measured as before, and the results showed that none of the gold seeds tested showed any leakage due to sterilization or other causes.

The tests showed that gold seeds supplied by the emanation plant at the Cancer Hospital on Welfare Island, and those of the commercial supply are of equal value as to quality, leak-proofness and sterilizability. By careful electroscopic measurements I have found gold seeds leak proof, even when boiled and sterilized in steam under pressure of 20 pounds.

In my opinion therefore, no justification exists for the statements spread through the literature to the effect that gold seeds, even if properly made, are leaky and not able to be sterilized by boiling or in steam under pressure.

COMMENT

Radon tubules in the form of gold "seeds" are practicable and useful in radiation therapy. They are leak proof and may be sterilized without fear of damage along with and in the same manner as surgical instruments.

Experience and scientific tests show that removable platinum seeds offer no advantage over gold seeds.

55 East Eighty-Sixth Street.

THE TREATMENT OF TRICHOMONAS VAGINITIS WITH ACETARSONE (STOVARSOL)

GEORGE GELLHORN, M.D., ST. LOUIS

The subject of trichomonas vaginitis has received adequate attention in this country only in the last few years. Today, however, it is common knowledge that a copious thin yellow vaginal discharge with small air bubbles and a disagreeable odor represents a condition that is separate and distinct from all other forms of vaginitis, the physical characteristics of this discharge the marked irritation of the vaginal mucosa and the intense discomfort are typical enough. To make the diagnosis absolutely certain, a drop of the discharge is diluted with a drop of water and examined under a cover glass or in the hanging drop and the trichomonads are easily recognized by their lively rotating motion.

Trichomonas vaginitis is intractable by the usual therapy of vaginal discharge. That fact is best evidenced by the large number of methods that have been recommended in the last few years no less than six different modes of treatment have been proposed. Most of these are based on very energetic mechanical and chemical cleansing and their very multiplicity suggests uncertainty of results.

I would hesitate to add yet another method if I were not in a position to submit a procedure which is based on an entirely different principle and which at the same time is extremely simple and highly efficacious. The credit belongs to Dr. L. D. Cady of this city, who called my attention to the possibilities of acetarsone (stovarsol).

Acetarsone is a synthetic arsenical that has been accepted by the Council on Pharmacy and Chemistry of the American Medical Association.¹ In this country and in France it is used largely in the treatment of amebic dysentery.² It was Dr. Cady's favorable experience with the drug that made him suggest its use in the treatment of another protozoic condition, namely, trichomonas vaginitis.

The question was merely: Does acetarsone, which heretofore has been given only by mouth, exert the same amebicidal prop-

Read before the St. Louis Medical Society, Feb. 14, 1933. The acetarsone (Stovarsol) used in this work was supplied by Merck & Co.

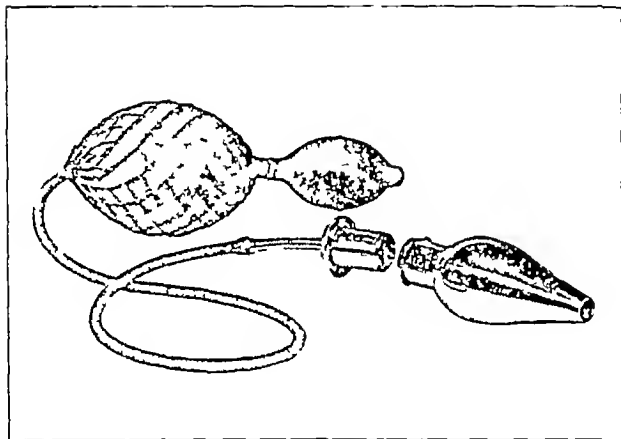

From the Department of Obstetrics and Gynecology, Washington University School of Medicine.

¹ New and Nonofficial Remedies, Chicago: American Medical Association, 1930, p. 81.

² Maxwell, C. H., Jr., and Glaser, Jerome: Treatment of Congenital Syphilis with Acetarsone (Stovarsol) Given by Mouth, *Am. J. Dis. Child.* 43: 1461 (June) 1932 (with extensive review of the literature).

erties when used locally? My first attempt along this line was highly encouraging, further trials followed, and, finally, a definite technic was evolved which has now been in use for more than eleven months. The preparation used is a compound of a light white powder which contains 12.5 per cent of acetarsone in equal parts of kaolin and sodium bicarbonate. The standard dose is 1 teaspoonful which contains $7\frac{1}{2}$ grains (0.5 Gm.) of the drug.³ It is introduced into the vagina by means of a specially designed powder blower, the construction of which is shown in the accompanying illustration. When the metal bulb is firmly held against the vaginal entrance, air pressure will smooth out all the folds and crevices, distend the vagina maximally and, at the same time, distribute the powder over the entire mucosa. As a rule from six to eight compressions of the rubber bulb suffice to empty the reservoir. Between each two compressions there should be a short pause, first to let the powder settle and, second, to let the air escape.

The treatment is repeated every second or third day. Douches are not permitted at any time. The subjective effect is very rapid. Patients almost invariably declare that after the first treatment the intense burning is lessened. Objective improvement follows with little delay in the majority of cases. After the second or third treatment, the discharge is reduced in amount and changed from the original thin yellow to a whitish more mucoid consistency. After the third or fourth treatment, the discharge disappears altogether. Of course there are some

Powder blower for distributing acetarsone compound over mucosa of vagina.

obstinate cases that require one or two additional treatments. Never have any toxic effects, local or systemic, been observed.

All writers on the subject of trichomonas vaginitis have emphasized the frequency of recurrences. The fact that, in the two cases of this sort which I have observed, the discharge reappeared after four months of perfect well being makes me suspect that I was dealing with a reinfection rather than a recurrence. To judge from the literature and my own observations, such reinfections not infrequently seem to follow an intestinal upset and be aggravated by an intervening menstruation. The latter, therefore, should not be permitted to interrupt the treatment. In fact, I have not only continued the procedure throughout the period but doubled the amount of acetarsone during that time.

Acting on the supposition of the intestinal origin of trichomonas vaginitis I have also given acetarsone by mouth as an attempt at prophylaxis but have not yet reached any conclusion as to its value. Rectal injections with acetarsone might be advisable in patients with a history of trichomonas vaginitis but with this I have had no personal experience.

The success obtained with insufflation of acetarsone proves that the principle of powder treatment is far superior to that of douching in trichomonas vaginitis. Others have come to the same conclusion, for instance, Sure and Bercey.⁴ It may

³ A practical prescription for the compound when only small quantities are needed is acetarsone 1 drachm (4 Gm.), kaolin $3\frac{1}{2}$ drachms (14 Gm.), sodium bicarbonate $3\frac{1}{2}$ drachms (14 Gm.).

⁴ Sure, J. H. and Bercey, J. E. *Am. J. Obst. & Gynec.* 25: 136 (Jan.) 1933.

also be possible that other powders will exert a curative effect in this particular form of vaginitis. I refer to the bismuth compounds because the pediatricians use them with success in a certain form of infantile colitis or proctitis in which large numbers of trichomonads are found.

My object in this paper is twofold: (1) to stress the advantages of the dry over the moist treatment in trichomonas vaginitis, (2) to call attention to the exceptional advantages of acetarsone in this condition.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS FORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary

CALCIUM GLUCONATE (See New and Nonofficial Remedies, 1933, p. 129)

Calcium Gluconate-Merck—A brand of calcium gluconate N. N. R.

Manufactured by Merck & Co. Inc., Rahway, N. J. No U. S. patent or trademark.

PHENOBARBITAL SODIUM (See New and Nonofficial Remedies, 1933, p. 96)

Phenobarbital Sodium-Merck—A brand of phenobarbital sodium-N. N. R.

Manufactured by Merck & Co. Inc., Rahway, N. J. No U. S. patent or trademark.

LIPIODOL-LAFAY (See New and Nonofficial Remedies, 1933, p. 232)

The following dosage forms have been accepted:

Capsules *Lipiodol Lafay*, 0.5 Gm. Each gelatin capsule contains lipiodol Lafay equivalent to 0.2 Gm. of iodine.

Dosage Two to five capsules daily after meals.

Tablets *Lipiodol Lafay*. Each tablet contains a calcium salt of the iodized fatty acids of lipiodol Lafay 0.1 Gm. (equivalent to 0.04 Gm. of iodine) incorporated in a base composed of sugar, acacia and cacao, and flavored with vanilla.

Dosage Two to five tablets daily.

SODIUM MORRHUATE—The sodium salt of the unsaturated fatty acids occurring in cod liver oil.

Actions and Uses—The action of sodium morrhuate is that of a sclerosing agent. It is employed in solution with addition of a local anesthetic for the obliteration of varicose veins.

Dosage—One half to 1 cc. of a 5 per cent solution.

Sodium morrhuate is a pale, yellowish granular powder possessing a slight fishy odor. It is soluble in water.

Incinerate about 1 Gm. of sodium morrhuate; the residue responds to test for sodium carbonate. Dissolve about 0.01 Gm. of sodium morrhuate in 10 cc. of water, add 1 cc. of chloroform followed by one drop of sulphuric acid and shake; a violet red color results, gradually changing to a reddish brown.

Dry about 1 Gm. of sodium morrhuate accurately weighed at 100 C. for six hours; the loss does not exceed 2 per cent. Weigh accurately about 1 Gm. of sodium morrhuate in a tared platinum dish, add 10 cc. of sulphuric acid, gently heat while fumes of sulphur trioxide are evolved; repeat using two portions of 2 cc. of sulphuric acid respectively; ignite, cool and weigh as sodium sulphate; the sodium found corresponds in not less than 7 per cent nor more than 7.8 per cent when calculated to the dried substance.

Transfer about 25 Gm. of sodium morrhuate to a suitable Squibb separatory funnel, add 350 cc. of water and sufficient diluted sulphuric acid to precipitate the fatty acids and extract with 3 portions of ether, using 150 cc., 100 cc. and 50 cc. respectively. The combined ethereal solutions evaporated to an oily liquid on the steam-bath conform to the following requirements:

Morrhuate acid, a component of sodium morrhuate, responds to the following tests for identity, purity and assay. Morrhuic acid occurs as a light amber oily liquid possessing a slight fishy odor and taste, soluble in alcohol, carbon tetrachloride, chloroform and ether, practically insoluble in water. The specific gravity is 0.898 to 0.907 at 25 C.

Incinerate about 0.5 Gm. of morrhuate acid accurately weighed; the residue does not exceed 0.2 per cent. Dissolve about 0.1 Gm. of morrhuate acid accurately weighed in a dry 500 cc. glass stoppered flask, add 10 cc. of chloroform, followed by the addition of 25 cc. of iodochloride test solution (Wijs modification), accurately measured, stopper the flask and allow to stand for thirty minutes in a cool place.

protected from light To the mixture add 20 cc. of a 15 per cent solution of potassium iodide mix thoroughly add 200 cc. of water previously boiled and cooled and titrate the excess of iodine with tenth normal sodium thiosulphate solution using starch paste as an indicator While the foregoing is being performed make a control test by using exactly the same quantities of reagents and titrate the free iodine with tenth normal sodium thiosulphate solution the amount of tenth normal sodium thiosulphate solution consumed corresponds to an iodine value of not less than 145 and not more than 185

Dissolve about 1 Gm. of morrhuae acid, accurately weighed in 50 cc. of alcohol and titrate with tenth normal potassium hydroxide solution using phenolphthalein as an indicator the amount of tenth normal potassium hydroxide solution consumed corresponds to a neutralization value which should not be less than 188 and not more than 198

Digest about 5 Gm. of morrhuae acid under a reflux condenser with a solution of about 2 Gm. of potassium hydroxide in 40 cc. of alcohol for an hour or until saponified Evaporate most of the alcohol dissolve the residue in 50 cc. of hot water transfer the solution to a separatory funnel rinsing the flask with 25 cc. to 50 cc. of hot water cool extract with ether using 2 portions of 50 cc. each adding if necessary about 5 cc. of alcohol to facilitate the separation of two liquids wash the combined ether extraction with small portions of water until not reddened by phenolphthalein transfer the ethereal solution to a tared beaker evaporate the ether on a water bath dry the residue at a temperature not exceeding 100 C and weigh the unsaponifiable matter does not exceed 1.5 per cent

Ampule Sodium Morrhuate 5% with Benzyl Alcohol (Searle)
5 cc. Each cc. contains 0.05 Gm. sodium morrhuate and benzyl alcohol 0.02 Gm. in aqueous solution

Prepared by G D Searle & Co Chicago No U S patent or trademark.

DEXTROSE (See New and Nonofficial Remedies, 1933, p 267)

The following dosage forms have been accepted

Ampule Glucose (U S P Dextrose) Solution 20 cc size A solution prepared by dissolving anhydrous dextrose in the proportion of 9 Gm. (equivalent to 10 Gm. dextrose-U S P) to 20 cc. of sterile distilled water

Prepared by Lederle Laboratories Inc. Pearl River N Y

Ampule Glucose (U S P Dextrose) Solution 50 cc size A solution prepared by dissolving anhydrous dextrose in the proportion of 22.5 Gm. (equivalent to 25 Gm. dextrose-U S P) to 50 cc. of sterile distilled water

Prepared by Lederle Laboratories Inc. Pearl River N Y

Ampule Glucose (U S P Dextrose) Solution 100 cc size A solution prepared by dissolving anhydrous dextrose in the proportion of 45 Gm. (equivalent to 50 Gm. dextrose-U S P) to 100 cc. of sterile distilled water

Prepared by Lederle Laboratories Inc. Pearl River N Y

REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS.

PAUL NICHOLAS LEECH Secretary

D C P 340 NOT ACCEPTABLE FOR N N R

According to a circular and form letter forwarded by a physician to the Council, D C P 340 is the name under which Parke, Davis & Company markets a preparation of dicalcium phosphate. Firms which have had dealings with the Council as long as Parke, Davis & Company are well aware of the Council's sound objections to the use of letters and numerals for, or in connection with, the names of medicinal products. The menace of such nomenclature to rational and intelligent therapy is too obvious to need further emphasis. It is indeed regrettable that a house of the standing long enjoyed by Parke, Davis & Company should be launching a preparation under such auspices. The facts that the letters are taken (apparently as a sort of slang abbreviation) from the chemical name of the product and that the number represents the mesh through which the preparation is sifted can hardly be pleaded in extenuation.

The product is apparently intended to exploit the current interest in calcium-phosphorus therapy or prophylaxis. The circular states "Bloom has demonstrated clinically that dicalcium phosphate is a well utilized calcium phosphate compound." Bloom's paper does not bear critical analysis as evidence for the clinical value of secondary calcium phosphate and since it is apparently the sole clinical evidence, the value of this therapy, not to mention the advantage of the secondary calcium phosphate over the tertiary, cannot be considered as being established. The circular cites the work and opinion of Sherman in support of the thesis that "the average American dietary is actually low in both of the factors [calcium and phosphorus]." The Council has held that this thesis is by no means established, New and Nonofficial Rem-

edies, 1933 p 129, states "The average normal diet usually contains just about enough calcium for the needs of the body."

Although in the circular the claim for the use of D C P 340 as a routine measure to insure adequate calcium intake is not explicitly stated, the inference of its value is clearly indicated in the light of present knowledge the claim is unwarranted. While there may be a place in medicine for the use of dicalcium phosphate in some conditions of recognized deficiency there is certainly no place in rational and scientific therapy for a preparation marketed under such a name as D C P 340.

The Council declared D C P 340 unacceptable for New and Nonofficial Remedies because it is a preparation marketed under an uninformative name with unwarranted claims of therapeutic or prophylactic value.

NIAZO NOT ACCEPTABLE FOR N N R

Niazo is the name applied by the Schering Corporation New York to a diazotized pyridine compound, stated to be 2-butyl-oxy-l-azo-2,6-diamino pyridine and recommended for use as a urinary antiseptic in the treatment of acute and chronic gonorrheal diseases and other bacterial infections of the urinary tract. In 1931, in accordance with the report of its Committee on Nomenclature, the Council voted to recognize the name Niazo, provided the Schering Corporation secure consent of the discoverer (or discoverers) and provided he (or they) do not authorize the use of any other name in the United States. Subsequently the Council adopted the referee's report holding on the basis of the clinical and pharmacologic evidence submitted by the firm, that Niazo was unacceptable because the therapeutic claims advanced for the product were not supported by adequate evidence and because unaccepted products were named in the advertising. At the request of the firm the Council agreed to postpone publication of the report to await new evidence.

In a later report, in April, 1932, the referee reviewed and analyzed all the available evidence on the efficacy of Niazo and concluded that the evidence supported the opinion that, because of its antibacterial adjuvant action Niazo has some value as a urinary antiseptic. The Council adopted the referee's recommendation that Niazo be accepted for one year provided the firm agree (1) to omit claims for general or specific bactericidal action in urine excreted after oral ingestion of Niazo (2) to omit claims for penetration of tissues (3) to omit claims for analgesic action (4) to limit claims for antiseptic action to bacteriostatic effects (5) to emphasize the fact that Niazo is chiefly valuable as an adjuvant agent in the treatment of infections of the urinary tract (6) to discontinue distribution of all advertising material for Niazo containing claims in conflict with these conditions and to submit all advertisements labels and pamphlets on Niazo to the Council before issuing them and (7) provided further, that the A M A Chemical Laboratory report favorably on the composition, tests and standards for Niazo.

This report was forwarded to the firm (April 28 1932) and in reply the firm agreed to comply with these conditions.

An advertisement of Niazo accompanied by a reprint of a paper by Dr Carl Rusche (*Am J Surg* 15 545 [March] 1932) was circulated among physicians by the firm in June 1932. In this advertisement it was claimed that Niazo was a "mainstay adjuvant" and a "valuable bacteriostatic aid in the treatment of genito-urinary infectious conditions." On the card sent to physicians Niazo was described as the new effective treatment for infections of the urinary tract. The firm's explanation of the issuance of this advertisement while Niazo was under consideration by the Council has been accepted.

The referee has again reviewed the evidence on the value of Niazo as a urinary antiseptic. During the past year, no new favorable evidence has been published, except the paper by Dr Rusche referred to. This paper, which was reviewed previously in manuscript, does not make extravagant claims for Niazo but does not justify the conclusions drawn from it. The Council decided to withdraw the limited conditions under which Niazo might be accepted for one year and voted to declare Niazo unacceptable for inclusion in New and Nonofficial Remedies because the available evidence does not show it to be an effective urinary antiseptic.

Committee on Foods

GENERAL COMMITTEE DECISION

THE COMMITTEE ON FOODS AUTHORIZES THE PUBLICATION OF THE FOLLOWING GENERAL COMMITTEE DECISION ADOPTED FOR ITS OWN GUIDANCE AND FOR THAT OF FOOD MANUFACTURERS AND ADVERTISING AGENCIES ON FOOD COMPOSITION AND FOOD ADVERTISING

RAYMOND HERTWIG Secretary

THE IDEAL LABEL FOR FOODS

The container label of foods should conspicuously present such information as will properly inform the public of the true nature and quantity of the food within the package. The public deserves to know the ingredients of the foods it purchases. There are no sound arguments justifying secrecy on the composition of foods. Label identification of foods is a most cogent influence for prevention of incorrect, deceptive or fraudulent advertising apart from the package container. A properly informative label lays the basis for good sound advertising, the only kind of advertising the public or the food industry can permit in its own interest.

Accepted foods among other things are intended to serve as examples of foods properly labeled in the interest of the public and of the food industry as a whole. As such examples they militate for the adoption of properly labeled foods throughout the food field and of good equitable advertising and competitive practices.

An illustrative diagram of an ideal food label is presented for the guidance of food manufacturers and represents the type of label the public expects in its own welfare.

IDEAL LABEL FOR FOODS (Skeleton outline for main panel faces)	
COMMON NAME OF FOOD	
Example	* (Statement of added minor ingredients)
	RICE FLAKES
	* (Flavored with sugar malt and salt)
—OR—

REPORTS OF THE COMMITTEE

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMOTION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

RAYMOND HERTWIG Secretary

JELKE GOOD LUCK CHOCOLATINE SPREAD

Manufacturer—John F. Jelke Company, Chicago

Description—Mixture of coconut oil, chocolate syrup (containing sucrose, cocoa, chocolate, salt, vanilla and tartaric acid), hydrogenated vegetable oil, whole milk, cottonseed oil and a stearin-glycerin derivative.

Manufacture—The manufacture is essentially the mixing of vegetable fats and inoculated milk with a chocolate flavored syrup containing sucrose, cocoa, chocolate, salt, vanilla and tartaric acid and a small quantity of emulsifying agent—a glycerin stearin derivative. The ingredients are softened in a blending machine. 0.5 per cent of the emulsifying agent is added

and mixed in, the chocolate syrup is added and mixed in. After the mixture is thoroughly blended, a small quantity of vanilla extract is added. The final mixture is stored in a cooling room for from twelve to sixteen hours to set firmly, after which it is printed in blocks and allowed to stand another twelve to sixteen hours before wrapping.

The manufacture is under government inspection.

Analysis (submitted by manufacturer) —

	per cent
Moisture	15.6
Ash	1.0
Sodium chloride (NaCl)	0.7
Fat (ether extract)	52.0
Protein (N × 6.25)	1.9
Reducing sugars as dextrose	9.7
Sucrose (copper reduction method)	11.6
Crude fiber	0.6
Carbohydrates other than crude fiber (by difference)	28.9
Caffeine	0.01
Theobromine	0.21

Calories—5.9 per gram 168 per ounce

Claims of Manufacturer—The product is for use as a spread for bread, as shortening and icing in baking, and as an ingredient in appropriate recipe preparations.

PROTEO BREAD

(MADE FROM GLUTEN, WHOLE WHEAT AND SOY BEAN FLOURS, WITH OTHER NUTRIENTS)

Manufacturer—Holsum Bakery Company, Fort Wayne, Ind.

Distributor—Proteo Foods, Inc., Chicago

Description—A bread for carbohydrate restricted diets containing water, gluten, soy bean and whole wheat flours, skim milk, yeast, fat, egg casein, salt, calcium acid phosphate and a yeast food containing calcium sulphate, ammonium chloride, sodium chloride and potassium bromate, prepared by the straight dough method (method described in THE JOURNAL, March 12, 1932, p. 889).

Analysis (submitted by manufacturer) —

	per cent
Moisture (entire loaf)	38
Ash	3.0
Fat	8.0
Protein (N × 6.25)	24.1
Reducing sugar as dextrose	2.5
Sucrose	0.0
Starch (diastase method)	16.0
Dextrins (acid hydrolysis)	2.0
Pentosans	2.2
Crude fiber	1.3
Carbohydrates available	20.5
Carbohydrates available and nonavailable other than crude fiber (by difference)	25.8
Calcium (Ca)	0.21
Phosphorus (P)	0.39
Iron (Fe)	0.005

Calories—2.7 per gram 77 per ounce.

Caloric value per 100 grams bread	
Carbohydrates (available)	80
Fat	72
Protein	96

Claims of Manufacturer—Especially prepared for carbohydrate restricted diets, lower in carbohydrates and higher in minerals (calcium, phosphorus and iron) than ordinary breads. The protein has high biologic value.

INTERNATIONAL TABLE SALT (IODIZED) PURITY TABLE SALT (IODIZED)

Manufacturer—International Salt Company, New York City

Description—Table salt containing added calcium carbonate (less than 1 per cent), sodium bicarbonate (less than 0.1 per cent) and potassium iodide (0.02 per cent).

Manufacture—International Free Running Salt (THE JOURNAL, July 2, 1932, p. 34) is admixed in a batch mixer with the stated proportions of calcium carbonate, sodium bicarbonate, and potassium iodide, and automatically packed in cartons.

Analysis (submitted by manufacturer) —

	per cent
Moisture	0.0
Iron oxide (Fe ₂ O ₃)	absent
Barium sulphate (BaSO ₄)	absent
Calcium sulphate (CaSO ₄)	0.55
Calcium hydroxide (Ca(OH) ₂)	0.00
Magnesium chloride (MgCl ₂)	0.02
Sodium chloride (NaCl) (by difference)	98.43
Potassium iodide	0.02
Sodium bicarbonate	0.08
Calcium carbonate	0.90

Claims of Manufacturer—This iodized salt is for all table and cooking uses of salt. The sodium bicarbonate tends to prevent loss of iodine; the calcium carbonate tends to pre-

serve its free running qualities. The iodine in the salt aids in preventing goiter caused by insufficient iodine in the diet. Used daily as the only salt on the table and in cooking, it richly supplements the iodine of diets deficient in that element and thus helps to protect against goiter.

DOLE HAWAIIAN FINEST QUALITY
PINEAPPLE JUICE (Unsweetened)
PARADISE ISLAND BRAND
DIAMOND HEAD BRAND
HONEY DEW BRAND
SWEET TREAT BRAND

Manufacturer—Hawaian Pineapple Company, Ltd., San Francisco

Description—Hawaian pineapple juice retaining in high degree the natural vitamin content of the raw pineapple.

Manufacture—The pineapple juice is obtained from two pineapple sources in the preparation of canned pineapple (1) the "Ginaca" machines and (2) the cooking kettles (see announcement of acceptance for Dole Hawaiian Finest Quality Pineapple (THE JOURNAL, April 8 1933, p 1106)

The juice is expressed from the shredded fruit, heated to 60 C by passing through a tubular heater centrifugated to remove suspended matter, filled into cans which are sealed under "vacuum" heated in a cooker (88 C) for less than ten minutes and promptly cooled. The heating time is reduced to a minimum to retain the natural flavor to maximum degree. Acid proof equipment is used.

Analysis (submitted by manufacturer) —

	per cent
Moisture	85.3
Ash	0.4
Fat (ether extract)	0.3
Protein (N \times 6.25)	0.3
Reducing sugars as invert.	8.6
Sucrose (copper reduction method)	3.7
Crude fiber	0.02
Carbohydrates (by difference)	12.8
Titrateable acidity as citric acid	0.9
Calcium (Ca)	0.02
Iron (Fe)	0.0005
Copper (Cu)	0.00017
Magnesium (Mg)	0.02
Manganese (Mn)	0.0003

Calories—0.6 per gram 17 per ounce

Vitamins—The heating of the juice prior to centrifugating, and the sealing under vacuum reduces incorporated air the heating time is short and the temperature low. These factors favor protection of the vitamins.

Claims of Manufacturer—For all uses of pineapple juice, largely retaining the natural nutritional values of raw pineapple (vitamin C slightly reduced). A good source of vitamins A, B and C.

AMAESSA FLOUR

Manufacturer—Texas Star Flour Mills Galveston Texas

Description—An 'all purpose' hard winter wheat patent flour

Manufacture—Selected hard winter wheat is cleaned scoured tempered and milled by essentially the same procedure as described in THE JOURNAL June 18 1932 page 2210. Chosen flour streams are blended.

Claims of Manufacturer—This flour is designed for home baking.

PFIZER SODIUM CITRATE U S P (VIII) PFIZER SODIUM CITRATE U S P (X)

Manufacturer—Charles Pfizer and Company, Inc New York City

Description—Sodium citrate U S P (VIII) ($2\text{Na}_3\text{C}_6\text{H}_5\text{O}_7 \cdot 11\text{H}_2\text{O}$) and U S P (X) ($\text{Na}_3\text{C}_6\text{H}_5\text{O}_7 \cdot 2\text{H}_2\text{O}$)

Manufacture—U S P (VIII) Citric acid U S P and sodium bicarbonate in definite proportions are dissolved in water. The solution is heated filtered, adjusted to a definite pH value, cooled and stirred until the crystallized sodium citrate is ready to be spun free from the mother liquor in a centrifuge. The crystals are washed with dilute citric acid solution and air dried at slightly above room temperature.

U S P (X) The manufacture is the same as that for U S P (VIII) excepting that a somewhat more concentrated solution is used and the crystallization occurs at a higher temperature.

Analysis (submitted by manufacturer) —

	per cent
U S P VIII	
Water of crystallization	27.7
Ash	44.5
Fat, protein sugars	0.0
Sodium citrate ($2\text{Na}_3\text{C}_6\text{H}_5\text{O}_7 \cdot 11\text{H}_2\text{O}$) not less than	99.5
U S P X	
Water of crystallization	12.3
Ash	53.7
Fat, protein sugars	0.0
Sodium citrate ($\text{Na}_3\text{C}_6\text{H}_5\text{O}_7 \cdot 2\text{H}_2\text{O}$)	99.0

Calories (submitted by manufacturer) —

U S P VIII	13 per gram	37 per ounce.
U S P X	16 per gram	45 per ounce. (International, Critical Tables 5 166)

Claims of Manufacturer—For use as emulsifier in cheese, as homogenizer in ice cream and whipping cream for adjusting the pH of food preparations, and for similar purposes.

SCOTCH BRAND PEARLED BARLEY

Manufacturer—The Quaker Oats Company, Chicago

Description—Pearled barley practically free of barley bran

Manufacture—Sound stain free barley is cleaned to remove chaff, weed seed and foreign matter and is pearled down to the size desired in a special pearling mill which removes the hulls and bran by scouring the barley between the peripheral surface of a revolving circular stone and the countermoving perforated wall of the machine. The pearled barley is separated from the flour, bran and hulls by air separators. The clean, pearled product is sized and automatically packed in cartons.

Analysis (submitted by manufacturer) —

	per cent
Moisture	9.9
Ash	0.7
Fat (ether extraction method)	0.7
Protein (N \times 5.83)	9.4
Crude fiber	0.5
Carbohydrates other than crude fiber (by difference)	78.8

Calories—3.6 per gram 102 per ounce

FISHERS RYE FLOUR

Manufacturer—The Fisher Flouring Mills Company Seattle

Description—A rye flour milled from Eastern dark rye, approximately 90 per cent of the grain.

Manufacture—The rye is cleaned, milled and about 10 per cent of the coarse material of grain removed.

Analysis (submitted by manufacturer) —

	per cent
Moisture	11.3
Ash	1.6
Fat (ether extraction method)	1.9
Protein (N \times 5.7)	13.2
Crude fiber	2.1
Carbohydrates other than crude fiber (by difference)	70.0

Calories—3.5 per gram 99 per ounce

Claims of Manufacturer—For bread baking.

QUAKER BRAND PUFFED WHEAT

Manufacturer—The Quaker Oats Company Chicago

Description—Ready-to-eat cooked and puffed durum wheat.

Manufacture—Durum wheat is cleaned, scoured cooked and steamed in a closed vessel called a gun. When the desired pressure has been reached, the lock that seals the gun is quickly withdrawn and the door is forced open by the internal steam pressure. The quick release of pressure causes a sudden conversion into vapor of the moisture within the wheat and puffs it to light porous grains. The wheat is screened, dried to 2 per cent moisture content, and packed in paraffin paper bags in cartons.

Analysis (submitted by manufacturer) —

	per cent
Moisture	2.0
Ash	1.4
Fat (ether extraction method)	1.5
Protein (N \times 6.25)	16.4
Crude fiber	2.0
Carbohydrates other than crude fiber (by difference)	76.7

Calories—3.9 per gram 111 per ounce.

Claims of Manufacturer—The wheat is steam exploded to eight times normal size.

THE CONTINUED USE OF DIGITALIS IN PATIENTS WITH REGULAR RHYTHM

It is not surprising that the continued use of digitalis by physicians in patients with regular rhythm has not been found to be of benefit. When should the use of digitalis be discontinued in patients with regular rhythm? Even the most experienced physician can only say that it seems occasionally to be of benefit in such cases. But the use of digitalis in heart disease deprecates its use in such cases. It is not because they are so common, but because there is no evidence that digitalis does up to 13 cc of the tincture daily, effects the progress of congestive failure, with regular rhythm at any stage in the course of the disease. This opinion from one who has had notable success in elucidating clinical problems by experimental methods, is based wholly on his clinical experience. Lewis scarcely refers to the use of the drug in his consideration of treatment of hypertension or of arteriosclerotic or valvular heart disease, he is content with clear instructions for its administration and continuation in auricular fibrillation, and for its trial, in the largest tolerated dose, in congestive failure.

Another view has been originated by a pharmacologist¹ who mentions patients between 50 and 60 years of age, with early signs of cardiac failure, "who retain for a long time excellent heart function by constant treatment with digitalis. As soon as digitalis is discontinued for two weeks, symptoms of cardiac insufficiency manifest themselves." This view is warmly supported by Christian,² who advises continuous digitalis medication (from 0.2 to 0.3 Gm. of leaf daily, lower doses if toxic symptoms appear) in all cases of cardiac enlargement or in cases presenting hypertension or valvular heart disease in which cardiac enlargement may be anticipated.

The pharmacologist has quoted clinical observation to support this mode of therapy, while the clinician, confronted with the difficulty of supplying adequate clinical evidence in the form of statistics of survival in comparable cases of early heart disease with and without digitalis therapy, has relied largely on animal experimentation.

Cloetta³ had interpreted his rabbit experiments of twenty-five years previously as indicating that continued digitalis medication of normal animals had no effect on heart weight. When experimental aortic insufficiency was present, however, hypertrophy was much less in the treated animals. Ignoring the loss of weight and the lassitude of animals treated with large doses of digitalis, he ascribed this to the cardiac action of the drug. Referring to this work later, he² not only emphasized the prevention or retardation of hypertrophy in rabbits with experimental valve lesions but intimated that digitalis decreases the heart weight of normal animals. Meanwhile, Herrmann⁴ had published his data on heart weight in 200 normal dogs and 70 with experimental aortic insufficiency, which showed how variable is the degree of hypertrophy produced by these lesions. In the light of this work Cloetta's experiments seem inconclusive, although his conclusion may be confirmed or disproved by experiments on adequate material and with doses of digitalis that do not interfere with nutrition or activity. While it cannot be regarded as proved that digitalis retards hypertrophy, there is ample proof that even in normal animals and men it diminishes cardiac work and diastolic heart volume and that, in experimentally damaged hearts, it probably "reduces the energy requirement of the heart or permits it to do more work with the same expenditure of energy."⁵ The evidence for this action, obtained by pharmacologists in England, Holland and Germany, has been fully confirmed by Cohn and his co-workers at the Rockefeller Institute. Convincing evidence that digitalis reduces heart volume of intact animals with normal or with damaged hearts came originally from Christian's clinic⁷ and it is now generally accepted. Dilatation everywhere regarded as the precursor and cause of hypertrophy, and a condition that diminishes dilatation should retard hypertrophy. Christian is probably justified in his belief that digitalis is a cardiac "lubricant," or of heart efficiency, and that it may be useful without having the subject to excessive heart failure.

Christian's view of digitalis as a cardiac lubricant is difficult to understand.

1 Lewis, Thomas. Diseases of the Heart. New York: Macmillan Company, 1933. pp. 29, 154, 155.
2 Cloetta, Max. The Biochemical Action of Digitalis. J. A. M. A. 93: 1462 (Nov. 9) 1929.
3 Christian, H. A. The Use of Digitalis Other Than in the Treatment of Cardiac Decompensation. J. A. M. A. 100: 789 (March 18) 1933.

an injurious influence on cardiac function, the heart, once enlarged, is already on its way to eventual failure." It may be recalled that, in dogs, hypertrophy due to aortic insufficiency occurs more quickly and to a greater degree in young than in old animals,⁸ and that the degree of hypertrophy in dogs killed from 145 to 500 days after the lesion has been produced is no greater than in those killed after from thirty to sixty days of aortic leakage. In many patients, similar phenomena occur, these have been concisely summarized by Lewis,¹ who concludes that hypertrophy due to overwork "does not constitute disease, it is physiological." He feels that while the overburdened heart fails rapidly, once failure occurs, the underlying cause is a change in the muscle "usual with advancing years, or associated with intercurrent infection, we do not as yet know with any degree of finality."

The practitioner who tries to analyze his own experience will not forget the psychic factor. Christian's patients who expected to feel better after taking foxglove felt better, but Stewart and Cohn's⁸ normal subjects, who knew that their cardiac output was reduced by the drug, experienced weakness and one third were dyspneic. Cardiac enlargement, hypertension or organic heart disease may be said to justify continued digitalis therapy for patients who expect medicine. Doses just under the toxic level can be taken for years without harm, and when the change in muscle occurs and failure sets in the heart is under the influence of the drug. If, as is generally believed, digitalis has power to benefit some cases of failure with regular rhythm, it should be more effective when given early. Yet a sound basis exists for the skepticism of those who refuse to put patients to the trouble and expense of years of medication while still in good health. They may well prefer to reserve the drug until symptoms are clear cut and their response to medication can serve as an index of the drug's effectiveness in each patient. Christian likens digitalis in patients with heart disease to thyroid in myxedema or to liver extract in primary anemia. These specifics are not given, however, until symptoms are apparent, even though they are continued throughout life thereafter. Moreover, patients with myxedema or primary anemia do not die of their disease if they receive early and continuous therapy, while many patients with congestive failure die in spite of early and adequate treatment with digitalis. This drug is not a specific, it is a valuable medicament which may safely be given early and continued through life. It can be withheld until symptoms warrant its trial. Should its continued use, before symptoms appear, become a generally accepted practice, the dramatic spectacle of its action in untreated cases of heart disease might no longer impress us, but some patients would enjoy longer freedom from congestive failure.

KIDNEY IMPAIRMENT AND EDEMA

When the kidneys cease to function adequately, a series of untoward symptoms ensue, followed inevitably by death. The immediate cause of death has not been established. If the different factors involved as a result of renal insufficiency were more clearly determined, it might be more readily possible to combat those which are most menacing and thereby prolong life or avert disaster. When the work of the kidneys is sufficiently impaired, a retention of waste products, notably the nitrogenous compounds commonly excreted in the urine, is certain to ensue. But this is by no means the only adverse situation that may arise. Edema and its attendant distressing manifestations also are common symptoms. However, there is considerable evidence that the edema of so-called acute nephritis does not necessarily depend on the kidneys. Complete nephrectomy is by no means always followed by edema. When lesions morphologically identical with those of acute Bright's disease are produced by certain toxic agents edema does not regularly occur. Thus it early became probable that a tissue factor, rather than a purely renal one, may play the decisive part in the genesis of edema. Widal and his followers assigned it to retention of sodium chloride.

The fundamental features under consideration here can be reproduced experimentally in animals by double nephrectomy. Under such conditions Brown-Sequard¹ years ago concluded that the accumulation of the nitrogenous waste products was not the only factor responsible for the appearance of uremic symptoms, the disturbance of the "internal secretion" of the kidney being a more powerful and active factor. Others subsequently gave some adherence to this early vague endocrine hypothesis, but it has not survived the tests of time. Many investigators have been surprised by the absence of edema in some species. For example, Allen, Scharf and Lundin,² in a report of a study of experimental nephritis, stated that total nephrectomy produces a condition which in dogs is acutely fatal, generally within a few days. Nitrogen retention and acidosis are demonstrable, but death occurs from weakness without edema, hypertension or any of the clinical phenomena of nephritis. The explanation seems now to be clear. Nephrectomized dogs begin to vomit on the second or third day, and diarrhea soon follows, which leads to dehydration and loss of chlorides. If this is prevented by injection of Ringer's solution, which supplies water and chlorides, life is prolonged, as has been clearly demonstrated by Lyon, Shafton and Ivy³ of Chicago.

Conceivably the development of edema in extreme renal insufficiency may serve to dilute the "toxins" or

SATURDAY, JUNE 3, 1933

THE CONTINUED USE OF DIGITALIS IN PATIENTS WITH REGULAR RHYTHM

Foxglove has been given a critical trial by physicians for 158 years, yet a definite solution has not been found for two questions concerning its use. When should the drug be started, and how long continued in patients with heart disease who have regular rhythm? Even British cardiologists, long skeptical of its use except in auricular fibrillation, now grant that it seems occasionally to benefit congestive failure in such cases. But Lewis,¹ in his recent book on heart disease, deprecates giving digitalis in heart cases "merely because they are heart cases." He states that there is no evidence that digitalis, in doses up to 13 cc of the tincture daily, affects the progress of congestive failure, with regular rhythm, at any stage in the course of the disease. This opinion, from one who has had notable success in elucidating clinical problems by experimental methods, is based wholly on his clinical experience. Lewis scarcely refers to the use of the drug in his consideration of treatment of hypertension or of arteriosclerotic or valvular heart disease, he is content with clear instructions for its administration and continuation in auricular fibrillation, and for its trial, in the largest tolerated dose, in congestive failure.

Another view has been originated by a pharmacologist² who mentions patients between 50 and 60 years of age, with early signs of cardiac failure, "who retain for a long time excellent heart function by constant treatment with digitalis. As soon as digitalis is discontinued for two weeks, symptoms of cardiac insufficiency make their appearance." This view is warmly supported by Christian,³ who advises continuous digitalis medication (from 0.2 to 0.3 Gm of leaf daily, lower doses if toxic symptoms appear) in all cases of cardiac enlargement or in cases presenting hypertension or valvular heart disease in which cardiac enlargement may be antici-

pated. The pharmacologist has quoted clinical observation to support this mode of therapy, while the clinician, confronted with the difficulty of supplying adequate clinical evidence in the form of statistics of survival in comparable cases of early heart disease with and without digitalis therapy, has relied largely on animal experimentation.

Cloetta⁴ had interpreted his rabbit experiments of twenty-five years previously as indicating that continued digitalis medication of normal animals had no effect on heart weight. When experimental aortic insufficiency was present, however, hypertrophy was much less in the treated animals. Ignoring the loss of weight and the lassitude of animals treated with large doses of digitalis, he ascribed this to the cardiac action of the drug. Referring to this work later, he⁵ not only emphasized the prevention or retardation of hypertrophy in rabbits with experimental valve lesions but intimated that digitalis decreases the heart weight of normal animals. Meanwhile, Herrmann⁶ had published his data on heart weight in 200 normal dogs and 70 with experimental aortic insufficiency, which showed how variable is the degree of hypertrophy produced by these lesions. In the light of this work Cloetta's experiments seem inconclusive, although his conclusion may be confirmed or disproved by experiments on adequate material and with doses of digitalis that do not interfere with nutrition or activity. While it cannot be regarded as proved that digitalis retards hypertrophy, there is ample proof that even in normal animals and men it diminishes cardiac work and diastolic heart volume and that, in experimentally damaged hearts, it probably "reduces the energy requirement of the heart or permits it to do more work with the same expenditure of energy."⁶ The evidence for this action, obtained by pharmacologists in England, Holland and Germany, has been fully confirmed by Cohn and his co-workers at the Rockefeller Institute. Convincing evidence that digitalis reduces heart volume of intact animals with normal or with damaged hearts came originally from Christian's clinic⁷ and it is now generally accepted. Dilatation is everywhere regarded as the precursor and cause of hypertrophy, and a drug that diminishes dilatation should retard hypertrophy. Christian is probably justified in his belief that digitalis is a cardiac "lubricant," or increaser of heart efficiency, and that it may be useful throughout life in those subject to excessive heart muscle strain.

Christian and Lewis also differ in regarding work and cardiac hypertrophy, in their relation to heart failure, from different angles. One³ states that "cardiac hypertrophy, instead of being a beneficent process, is

an injurious influence on cardiac function, the heart, once enlarged, is already on its way to eventual failure." It may be recalled that, in dogs, hypertrophy due to aortic insufficiency occurs more quickly and to a greater degree in young than in old animals,⁵ and that the degree of hypertrophy in dogs killed from 145 to 500 days after the lesion has been produced is no greater than in those killed after from thirty to sixty days of aortic leakage. In many patients, similar phenomena occur, these have been concisely summarized by Lewis,² who concludes that hypertrophy due to overwork "does not constitute disease, it is physiological." He feels that while the overburdened heart fails rapidly, once failure occurs, the underlying cause is a change in the muscle "usual with advancing years, or associated with intercurrent infection, we do not as yet know with any degree of finality."

The practitioner who tries to analyze his own experience will not forget the psychic factor. Christian's patients who expected to feel better after taking foxglove felt better, but Stewart and Cohn's⁸ normal subjects, who knew that their cardiac output was reduced by the drug, experienced weakness and one third were dyspneic. Cardiac enlargement, hypertension or organic heart disease may be said to justify continued digitalis therapy for patients who expect medicine. Doses just under the toxic level can be taken for years without harm, and when the change in muscle occurs and failure sets in the heart is under the influence of the drug. If, as is generally believed, digitalis has power to benefit some cases of failure with regular rhythm, it should be more effective when given early. Yet a sound basis exists for the skepticism of those who refuse to put patients to the trouble and expense of years of medication while still in good health. They may well prefer to reserve the drug until symptoms are clear cut and their response to medication can serve as an index of the drug's effectiveness in each patient. Christian likens digitalis in patients with heart disease to thyroid in myxedema or to liver extract in primary anemia. These specifics are not given, however, until symptoms are apparent, even though they are continued throughout life thereafter. Moreover, patients with myxedema or primary anemia do not die of their disease if they receive early and continuous therapy, while many patients with congestive failure die in spite of early and adequate treatment with digitalis. This drug is not a specific, it is a valuable medicament which may safely be given early and continued through life. It can be withheld until symptoms warrant its trial. Should its continued use, before symptoms appear, become a generally accepted practice, the dramatic spectacle of its action in untreated cases of heart disease might no longer impress us, but some patients would enjoy longer freedom from congestive failure.

KIDNEY IMPAIRMENT AND EDEMA

When the kidneys cease to function adequately, a series of untoward symptoms ensue, followed inevitably by death. The immediate cause of death has not been established. If the different factors involved as a result of renal insufficiency were more clearly determined, it might be more readily possible to combat those which are most menacing and thereby prolong life or avert disaster. When the work of the kidneys is sufficiently impaired, a retention of waste products, notably the nitrogenous compounds commonly excreted in the urine, is certain to ensue. But this is by no means the only adverse situation that may arise. Edema and its attendant distressing manifestations also are common symptoms. However, there is considerable evidence that the edema of so-called acute nephritis does not necessarily depend on the kidneys. Complete nephrectomy is by no means always followed by edema. When lesions morphologically identical with those of acute Bright's disease are produced by certain toxic agents, edema does not regularly occur. Thus it early became probable that a tissue factor, rather than a purely renal one, may play the decisive part in the genesis of edema. Widal and his followers assigned it to retention of sodium chloride.

The fundamental features under consideration here can be reproduced experimentally in animals by double nephrectomy. Under such conditions Brown-Sequard¹ years ago concluded that the accumulation of the nitrogenous waste products was not the only factor responsible for the appearance of uremic symptoms, the disturbance of the "internal secretion" of the kidney being a more powerful and active factor. Others subsequently gave some adherence to this early vague endocrine hypothesis, but it has not survived the tests of time. Many investigators have been surprised by the absence of edema in some species. For example, Allen, Scharf and Lundin,² in a report of a study of experimental nephritis, stated that total nephrectomy produces a condition which in dogs is acutely fatal, generally within a few days. Nitrogen retention and acidosis are demonstrable, but death occurs from weakness without edema, hypertension or any of the clinical phenomena of nephritis. The explanation seems now to be clear. Nephrectomized dogs begin to vomit on the second or third day, and diarrhea soon follows, which leads to dehydration and loss of chlorides. If this is prevented by injection of Ringer's solution, which supplies water and chlorides, life is prolonged, as has been clearly demonstrated by Lyon, Shafton and Ivy³ of Chicago.

Conceivably the development of edema in extreme renal insufficiency may serve to dilute the "toxins" or

other harmful retained components and thereby render them less noxious. Investigations at the Northwestern University Medical School in Chicago by Barry, Shaf-ton and Ivy⁴ indicate that the prolongation of life is due primarily to maintenance of the normal water-sodium chloride balance in the body, and not to a dilution by edematous fluid of the urinary or toxic substances retained. The retention of urinary products per se in the presence of hypochloremia (chiefly sodium chloride) is not conducive to edema, even when adequate water is supplied, this confirms the contention of Widal. In order to obtain a retention of water adequate to prevent dehydration sufficient sodium chloride must be given to prevent hypochloremia, if an excess is given, edema results. The Chicago physiologists point to the important role assumed by sodium chloride and the rather minor role of water and the products of nitrogenous retention in the production of edema. In the presence of marked nitrogenous retention, water in "balanced" amounts is not retained in the body if the blood chlorides are subnormal. By keeping the intake of water constant and controlling the intake of sodium chloride, one can control the presence or absence of edema.

MELANOGENESIS

Pigmentation of the melanin type has long been known as a manifestation of both normal and pathologic conditions in man, yet our knowledge of its origin remains indefinite. It has seemed unlikely that cells which do not normally form melanotic pigment can acquire the power to produce the characteristic coloration under pathologic conditions. The appearance of the pigmentation in freckles, in melanotic tumors, and perhaps in Addison's disease, has been attributed to the overproduction of the coloring substance by cells that are ordinarily capable of producing it. The old theories of its origin from hemoglobin, the respiratory pigment of the blood, have been abandoned. Among the more recent views is that of Bruno Bloch,¹ who found that the occurrence of melanin in the skin corresponds to the location of cells with the capacity of oxidizing di-oxyphenylalanine. This has been termed the "dopa" reaction, by way of abbreviation, and it has been assumed that an enzyme plays an important part in melanogenesis. The alleged characteristic phenomena of enzyme action have in turn been denied because of the significant observation that the dopa reaction and also postmortem pigmentation can be obtained in sections of boiled skin.

Meanwhile, recent studies in biochemistry have directed attention to other types of oxidation-reduction reactions, notably such as involve the sulphur-containing glutathione. The sulphhydryl compounds are

considered typical models for the study of hydrogen transfer from one body to another. Being constituents of the cells, they act as acceptors and donors, thus regulating the cellular metabolism. According to Ropshaw,² at the Western Reserve University School of Medicine, Cleveland, there now is support of the view that melanogenesis is an intracellular process and a physiologic function of the pigment cell. It results from the reaction of cystine on protamine and is therefore limited in the skin to the epithelial layer, the only one containing sulphhydryls.

Ropshaw regards melanogenesis as nature's micro-color reaction in which the cysteine-cystine complex acts as an indicator and evidences a phase of nuclear metabolism, viz., the cleavage of protamine and its diffusion into the cytoplasm. Cysteine, he states, is present in the cytoplasm within the more complex body, the tripeptide glutathione, and protamine is present in the nucleoprotein (chromatin). Through cleavage due to cell enzymes these two substances are freed and brought in contact. In vitro a black precipitate is formed when protamine and cystine are brought together in a proper medium. The color reaction just described is reversible, the pigment becoming colorless in time. This may explain the disappearance of melanin or pigment elimination in the form of colorless products. It may be possible to extend the new theory to the phenomena of *albinism*, *postmortem pigmentation*, and the effect of light on the skin. For the present, however, there still are sufficient uncertainties in Ropshaw's views on melanogenesis to restrain added speculation.

Current Comment

PLACENTAL TRANSMISSION OF VITAMIN A

Discussions of the problems of maternal diet during pregnancy and lactation have as a rule been concerned more with the indirect effects on the fetus and the postpartum food, milk, than with the mother. After all, the maternal organism itself must be depended on in large measure to meet the nutritional problems of the young from the time of conception until weaning. That is why the various physiologic devices incident to the entire period of development in close affiliation with the maternal organism are of such great interest. They involve some surprising peculiarities. For example, as there is no direct connection between the maternal and the fetal circulation, the functions of the placental barrier are significant. Can all essential nutritive components pass through the intervening membranes to support the fetus? There has been considerable debate, for instance, as to whether fats can penetrate the placenta, though Sinclair¹ has recently declared

that such a transfer is possible. The new-born infant presents the surprising feature of an unusually liberal store of iron, which tends to avert the danger of anemia provoked by the paucity of this element in milk. Lately, with the growing appreciation of the role of vitamins in nutrition, questions have arisen with regard to the potential supply of these food factors to the young. A recent writer² has pointed out that there are two ways in which a young mammal may receive an endowment of vitamin A before it is weaned. The vitamin A may pass through the placental barrier into the fetal circulation during gestation, or it may be ingested by the nursing in the colostrum and the milk. Dann's² studies in the Nutritional Laboratory at the University of Cambridge, England, suggest that the amount of vitamin A in the liver at birth is small. Judging by his experience with animals the store in the new-born infant cannot readily be increased by fortifying the maternal diet with rich sources of vitamin A or its precursor carotene. Placental transmission is thus not pronounced. As is well known, however, the milk of the lactating mother can be enriched in vitamin A by a suitable diet. Under such conditions, nurslings can profit greatly by the vitamin that has passed into the milk. There is a practical aspect here. According to Dann the best way of applying vitamin A therapy with the object of giving the child a reserve of vitamin A is to dose it directly. Failing this, the best results may be expected to follow from giving the mother regular fairly high doses of vitamin A during the period of nursing. To give the mother vitamin A during pregnancy will not affect the vitamin store of the child to any noticeable extent.

CONTRAINDICATED VACCINES

Serologists have long been familiar with the "negative phase" of specific immunity, the precipitous fall in specific antibody titer on the injection of the corresponding vaccine into laboratory animals. This subimmunity is usually transient, being followed in most cases by the establishment of a new and higher level of immunity. The possibility that this negative phase may contraindicate specific vaccine therapy in certain rapidly progressive infectious diseases was suggested about six years ago by Felton and Bailey¹ of Harvard Medical School. The Boston investigators showed that the injection of specific pneumococcus products into laboratory animals causes an immediate and apparently specific lowering of their natural resistance to the pneumococcus sufficient to increase by a hundredfold their susceptibility to simultaneously injected pneumococci. An even more striking negative phase or anti-therapeutic effect is reported by Sia and Zia,² of the Peiping Union Medical School. Few if any symptoms were demonstrable by them on the injection of sublethal doses of low-virulent pneumococci into normal rabbits. Similar doses injected into rabbits previ-

ously treated with homologous pneumococcus filtrates, however, led to a rapidly increasing bacteremia, which was usually fatal. In order to simulate this increased fatality in unvaccinated control rabbits, it was necessary to multiply the routine infectious dose from 10,000 to 100,000 times. It is conceivable that these data from the use of relatively large doses in highly susceptible laboratory animals give an exaggerated picture of the clinical dangers. The theoretical possibility of this danger, however, should not be ignored by the proponents of specific vaccine therapy.

Medical Economics

PRIVATE GROUP PRACTICE

[This is the third and concluding part of a series of investigations conducted by the Bureau of Medical Economics of the American Medical Association. The first part was published in THE JOURNAL May 20 and the second part May 27.]

METHODS OF PAYMENT

Does group practice tend toward the establishment of a fixed market price for medical services? Is it a step toward group periodic payments or insurance? There have been frequent affirmative answers to both these questions by those who reason in the field of medicine from industrial analogies.

To secure information on the first point the question was asked: 'Is there a flat or maximum rate for general diagnosis?' It was assumed that if any system of flat rates was in use it would apply to this service. Several who made affirmative replies explained that the flat rate applied only to laboratory tests or to certain limited examinations. Such replies were counted as placing the group in the list of those having a flat rate for diagnosis, which probably makes that number larger than is correct. Of the 239 groups reporting, 15 failed to answer this question. Thirty-six of the 224 groups that answered stated that they had some sort of a flat rate for diagnosis, and 188 had no such rate. That less than 15 per cent of the groups had fixed a flat rate even for an original examination and diagnosis would seem to indicate little tendency to establish standard prices.

It is worthy of notice that a number of groups volunteered information to the effect that they tried to approximate local fee schedules, charged customary rates for the locality and adjusted fees to meet the incomes of the patients.

The same 224 groups replied to the question, "Has the group tried any arrangement for service in return for regular periodic payments?" Only twenty reported any such arrangement. The location of these indicates that the adoption of such plans was due more to local conditions than to any general policy. There were five groups in the state of Washington, four in California, three in Colorado and one each in Alabama, Arkansas, Indiana, Michigan, Oregon, Texas, Utah and Wisconsin.

Comments indicated that some of these arrangements were in the nature of contracts with a single firm to care for its employees and that the service given was confined to industrial accidents and care at the plant. That less than 9 per cent of the groups had ever tried any such plan and that 60 per cent of these were in three states in which this form of practice is highly developed furnish ample proof of a lack of any high correlation between group practice and sickness insurance, and also of the absence of any pronounced trend in that direction among groups.

Some of the following comments from groups not using insurance methods suggest that the attitude of physicians within the groups is much the same as that of those outside.

We are all bitterly and uncompromisingly opposed to any form of group insurance practice that interferes in any way with the individuality of the private physician.

We are entirely opposed to that type of practice.

We believe that this sort of medicine is absolutely detrimental because it gives the recipient a sense of security which he does not have eventually.

² Sia, R. H. P. and Zia, S. H. *Proc. Soc. Exper. Biol. & Med.* 29: 791 (April) 1932.

We have been very active in the campaign to keep that out of this district. If we enter into the practice it will be because local conditions force us in—not because we approve it.

Not by a whole lot That is a breeder of pests

LAY EMPLOYEES IN GROUPS

Information as to the number of lay employees was furnished by 230 groups. Owing to a lack of any uniform arrangement between hospitals and groups, when there is any integral connection, the groups which reported control or ownership of a hospital by a group or of a group by a hospital corporation were separated from those operating independently.

Table 8 shows the distribution of the various classes of employees between these two group divisions. No really worthwhile conclusions can be drawn from this table further than

TABLE 8—Distribution of Lay Employees Among Groups

Group Not Owning Hospital	Nurses		Laboratory		Business		Other	
	Number Groups	Number Employed	Number Groups	Number Employed	Number Groups	Number Employed	Number Groups	Number Employed
Employing	113	231	131	226	152	420	89	257
Not employing	47		29		8		71	
Owning Hospital								
Employing	57	323	55	107	63	198	45	363
Not employing	13		15		6		23	

a confirmation of the conclusion already made evident by various other facts—that there is no important feature of group practice which is in any way standardized and that every statement concerning the form or effects of such practice which assumes the existence of any generalization concerning the character of such practice is to be viewed with suspicion.

The possible variations in the relations of hospitals and groups seem to have been almost exhausted. Sometimes the group as a whole and sometimes one or more members own the hospital, or the hospital corporation may own the group and rent it office space. Again, a closed staff forms a group and operates without formal financial relations with the hospital or with almost all varieties of such relations. Several groups reporting no nurses, laboratory workers or business employees in their organization either directly stated, or the answers implied, that they made use of hospital facilities or vice versa. In other cases it is apparent that all the employees, even student nurses, have been included as employees of the group owning or controlling the hospital.

There is the possibility that in so large a sample of group practice as is included in these figures, errors of this kind tend to cancel each other thus to give a validity to the totals which is absent from the details. With this possibility in mind, but with emphasis on the inherent inaccuracy, the totals are offered for whatever value they may have.

The total number of lay employees in the 160 groups not owning or controlling hospitals is 1,314. There are 951 physicians in these groups or an average of 14 lay employees to each physician. In the groups owning or controlling hospitals the corresponding figures are 1,050 lay employees and 428 physicians, with 25 employees per physician. Combining the 2 classes there are 230 groups with 2,364 employees and 1,379 physicians, or an average of 17 employees for each physician. This also gives an average of almost exactly 10 lay employees per group.

DENTISTS IN GROUPS

Although it must be admitted that there are few facts that can be definitely presented to justify the conclusion, there would seem to be an increasing tendency to include dentistry as one of the specialties of group practice. Seventy-six groups reported that one or more dentists (a total of ninety-six) are members of groups or more or less closely affiliated. The nature of the connection varies widely. In some cases they are integral members of the group but this statement again has little meaning, owing to the variety of relations existing among those who are included as members.

From various comments and explanations it is clear that many of the dentists have special financial arrangements and

are frequently exempted from any fixed methods of income distribution that may apply to the medical members of the group. Probably because of the more standardized character of dental work and its greater isolation in practice a larger percentage of the dentists than of the physicians in groups have their income more directly dependent on their individual work.

In several instances the dentist was described as "affiliated" with a group, with no further explanation of the character of this relation. In other cases it was explained that the dentist rented office space from the group organization and conducted his own financial relations with his patients.

RATIO OF EXPENSES TO PHYSICIAN'S INCOME

One of the questions most frequently raised in regard to group practice is whether pooling of the expense for equipment and operation reduces the percentage of gross income expended for these purposes. It was manifestly impossible to obtain detailed, uniform financial reports from a sufficient number of groups to be representative. Instead two questions were asked: "What percentage of the total income is distributed to physicians?" and "What percentage goes for nurses and lay employees, administration, investment in and maintenance of plant?"

The sum of these two figures was 100 per cent except in a very few cases, which were excluded from the study. Manifestly, if it is desired to know the division of the total gross and net income of all the groups reporting, these separate percentages will give no information. Averaging, or combining in any other way, percentages calculated on differing bases does not show anything concerning the bases from which the original percentage was derived.

But if one considers these percentages as representative of individual groups, then medians and averages show the prevailing condition and give a fairly accurate picture of the general situation as to the ratio of expenses to gross income in group practice. Information was furnished on this point by 142 groups. This is the smallest number of replies received to any inquiry on the questionnaire, but is several times the number of groups used as a basis for any previous calculation on this point. Moreover, the replies are sufficiently well distributed geographically and as to size of groups to be fully representative.

It is a generally accepted rule in the interpretation of questionnaires that replies giving estimates are apt to be over-optimistic and to some extent reflect hopes and wishes. It should also be noted that a number of those who did not reply

TABLE 9—Net Income Distributed to Physicians

Size of Group	Number Groups	Average per Cent	Median per Cent
3	34	60	65
4	23	58	55
5	22	59	60
6	7	51	50
7	14	57	55
8	11	53	60
9	7	55	65
10	7	62	58
Over 10	17	58	60
Total	142	58	60

to these questions with any definite estimates volunteered comments to the effect that all income was going into expense or that the group was operating at a loss.

With these explanations table 9 is offered to show the average and median percentages of gross income distributed to physicians in these groups, according to the size of the groups.

The average for the 142 groups is 58 per cent, and the median, computed from an equal number of groups with a higher and lower percentage, is 60 per cent. The question of whether increasing the size of the groups reduces the overhead relative to income is clearly answered in the negative. There is no trend visible in relation to size in either averages or medians.

The other question, already asked, as to whether pooling expenses in a group reduces the percentage of gross income which must be expended to conduct a practice may be answered by comparing these figures with those obtained from a study of gross and net incomes in individual practice.⁶ In this study it was determined that the net income of individual practitioners varied according to the size of the city, from 66 to 73 per cent of the gross and that "there is a tendency for the net income of general practitioners to be about 67 per cent of gross income."

From this comparison it would seem to be fair to draw the conclusion that from 7 to 9 per cent less of the money paid by the patient goes to the physician in group than in private practice. This confirms the previously quoted opinion of a majority of secretaries of county medical societies that group practice does not afford a method of reducing the cost of medical care.

This conclusion was arrived at by E. P. Sloane in 1929, who said:⁷

There is no economic side to ethically conducted group clinics from the standpoint of increased revenue. The doctors who organize a group with the expectation of thereby producing either through increased number of patients or larger fees a larger joint income than the combined income of the different members would be if practicing individually are doomed to disappointment. From the standpoint however of economy in providing facilities for thorough and complete examinations and competent service diverse and varied as diagnosis, medical treatment, eye, nose and throat surgery, bacteriology, X-ray pathology, pediatrics, obstetrics, neurology, etc., there may be distinct economic advantage in co-operation in a group clinic to both its members and to the patient.

The secretary of the Wisconsin Medical Society expresses the same opinion:⁸

Wisconsin has as many clinic groups or medical service centers as any other state of like medical facilities. It is my judgment that practice in many of these groups is not clinic practice as that term is generally understood by the medical profession but that they are in fact associations of physicians representing various interests in medicine who have grouped themselves about a single unit for convenience, presumed economy and prestige. Where such medical centers were erected prior to 1929 the majority now find themselves with a heavy overhead that cannot be contracted to meet changed economic conditions. In general it is my judgment that physician members of most clinics have been hit harder by the economic stringency than any others except specialists who received high incomes.

It would appear therefore that these facts justify the conclusions of Samuel C. Harvey⁹ of the Yale University School of Medicine, who said:

It is stated that services of the family physician can be improved by coordinating him in a group together with the specialist in association with and under the control of a non-profit making corporation such as a hospital. The assumption is that the consumer requires in a majority of instances the services of various specialists and of an expensive plant, this making it more economical to bring at once the family physician and his clients to a central point where these are available. Moreover, it is also assumed that by such organization the requisite service could be provided far more economically than is done now.

The majority of family physicians at the present time practice from their homes where the overhead for office rent, transportation and incidental expenses is to a considerable extent included in the necessary charges for shelter, transportation and other needs of himself and family. Moreover, the expense of setting up the necessary office equipment and apparatus for the care of illness with which he deals is minimal. In other words, the charges of a plant are a very small fraction of the cost of his service. To bring him into a group renders these fixed charges a major fraction of the cost of his services and the net result must be either increased charge for service or less net return to the physician.

From the standpoint of the consumer it means that in 80 per cent of his contacts with the family physician the distance traversed to obtain his care is greater in order that in the remaining 20 per cent in which he needs the services of the specialist the distance may be shorter. Only by the greater use of the specialist for matters properly belonging to the family physician can such grouping be justified, but the proposition that presumes to provide more expensive service while at the same time lowering the cost is within itself incompatible except by involving the mystic word organization.

This question of economy of operation has been stressed because an assumed superiority of group practice in this respect has been the basis of arguments, resting on commercial analogies, that this greater economy and resulting superior competing power would cause groups gradually to supplant

individual practice. If, as now appears to be probable, group practice lacks this superiority, the question of its growth relative to other forms of practice must depend for its answer on the effect of other features.

These facts also seem to indicate that group practice does not reduce the cost of medical care to the patient.

DISTRIBUTION OF INCOME AMONG GROUP MEMBERS

So great is the diversity of plans for the distribution of net income among the members of the groups that any attempt to classify these plans into clearly distinguished types is impossible. There were 200 groups that described the methods used in the distribution of income among the members. An attempt is made to group these as accurately as possible in somewhat broad and indefinite classifications in table 10. These classifications are those made in the replies from the group, even though comments and explanations sometimes suggested another classification. It is of course, clear that the first three classes are all of the same type, and comprise fifty-five groups in which the net income is determined by some plan fixed in advance. Yet there are considerable individual variations

TABLE 10—Distribution of Income Among Members

	Number Groups
Fixed percentage	44
Equal division	39
According to shares owned	2
All salaries	29
Salaries except to owners	29
Percentage to partners other salaries	10
Salaries and surplus	4
Salaries with surplus to shareholders	1
Individual	24
Percentage based on incomes	15
Special	3
	200

Several reports added that one or more physicians, sometimes described as on trial for admission to full group membership, are on salary or have special arrangements.

One group in this class reported:

At the formation of the group a set figure for each man was agreed upon. In case the income is below the estimate each man receives his pro rata share. In case there is more income than the estimate it is divided equally among the seven members.

Others said:

Divided on a pro rata basis according to what the group feels each individual is worth in terms of ability and years of experience.

Partially on a percentage and other personal.

The net profits are distributed as a salary distribution on a fixed percentage basis. The basis for members of the corporation is changed from time to time as circumstances require. A small number of assistants and fellows are on a definite salary for a maximum period of three years.

The next five classifications comprise those groups in which the distribution is primarily on a salary basis. There are seventy-three of these, and it is certain that in most instances there is some sort of secondary distribution of any sums in excess of salaries, at least in prosperous times. Even in the twenty-nine cases in which it was reported that all members were paid by salaries there were many comments which showed that these salaries were supplemented by other considerations. Sample explanations follow:

Each physician is paid salary amount based on amount of each physician's income.

Salary allowance to each member of the group and after that the money is divided as profits.

Percentage and salary.

Surplus over salaries and reserve funds, insurance, etc., divided equally among senior members.

Each member makes his own charges through hospital office. He is paid a monthly salary and at the end of each year is paid an additional sum to make his income 50 per cent of his total charges. This is paid provided the income to the hospital from his work equals not less than 75 per cent of his total charges. Should there be any profit after this it is either carried as a surplus or distributed as dividends. Should there be a deficit it is overcome by an assessment of each member of the group.

All physicians on salaries. Balance of income after expenses are paid is divided according to ownership in building and equipment.

⁶ Leland R. G. *Income from Medical Practice*. J. A. M. A. 96:1683 (May 16) 1931.

⁷ Report to Council Wisconsin State Medical Society, Jan. 7, 1933, pp. 23.

⁸ Harvey S. C. *Oikonomia Medika*. Yale J. Biol. & Med. 5:333-334 (March) 1933.

There is practically no real difference between those reporting all salaries and "salaries except to owners." As the quoted explanations show, some might, with almost equal accuracy, have been placed in the class in which incomes are determined by a fixed percentage.

Two co partners equally—all others on salary

Institution owned by _____ and _____ All others on salary with bonus Salaries range from \$300 to \$500 per month. Bonus determined from private practice collections

Three senior staff men share equally in net profits if any Three junior staff men on salary basis with bonus

I am the sole owner of the building and also all the equipment. The dentist pays me rent and collects his own accounts With E E N T man after the rent and overhead expenses have been deducted the net income is turned over to him. The pediatrician is doing my laboratory work in payment for rent and a share of the expenses of the office. The internist is paid for each consultation separately by the patient My assistant is on a salary

Percentage to two members. Salary and commission to two members'

The net is divided after general expenses are paid The new associate is put on a salary of \$300 to \$400 per month for probation period of two or three years If satisfactory he is permitted to join the organization on the basis of an increasing percentage each year until the full percentage equal to the highest is reached at the end of twelve or fifteen years

New member goes on a salary for about one year if then mutually satisfactory he is placed on a percentage basis planned to represent his work value and usefulness This percentage increases at intervals it is planned to bring all men to an equality eventually

There were thirty-nine groups that reported that incomes were determined by the individual earnings of the physicians. It may be noticed that this is eight less than the number that reported that financial relations with patients were with individual physicians. The explanation is that five of the 47 so reporting did not confirm this relation by replying to the question as to distribution of income, and three are included under "special." As far as can be determined from the accompanying explanation, there would seem to be little significance in the division between "individual" and "percentage based on incomes." It is probable that in most cases the distinction consists in a common collection system in the latter classification, and a deduction of common expenses before the amount collected is returned to the individual physician. However, there is not sufficient information to assure any such conclusion.

In the three "special" cases an endowment supports all or a large part, of the required equipment and general expenses, and the physicians receive their individual earnings. There are therefore forty-two groups in which the division of income is on the basis of individual earnings.

All efforts to find any correlation between the method of distribution of income and the size of the group or other characteristics failed. All methods seemed to be present in each size and form of organization.

One conclusion which may safely be drawn from this great diversity in the methods of distributing income is that the personal relations, preferences, prestige and other individual characteristics of the members of the groups and their relative bargaining and earning power and organizing ability are the dominant forces in determining the form of organization of each group, and that there is no apparent sign of any tendency to approach a definite type or fixed model.

REASONS FOR FAILURE OF GROUPS

Addresses were furnished for a number of groups, which, when investigated, were found to be no longer in existence. Many of the secretaries of county medical societies also reported that groups formerly operating in their locality, had been discontinued. In all these cases a letter was sent either to the secretary or to a former member of the group, asking the reasons for the discontinuance of group practice. The percentage of replies was naturally much smaller than to any of the other inquiries sent out, but those received throw considerable light on certain phases of group practice.

The replies which simply checked questions as to possible causes gave the following reasons for failure "insufficient patronage," two groups, "failure of one member to do his share of work," one, "personal differences among clinic members," three, "attitude of outside physicians," two. Comments on the last cause mentioned were "Not jealousies but desire for the best." "Outside physicians had nothing to do with them, as clinic used the group to promote business and attract it to themselves."

A number of replies gave further details concerning individual groups, which give so clear a picture of some of the forces that have caused the dissolution of groups as to deserve quotation.

The secretary of a county medical society said

There were two organizations for group practice in this city. Both have been discontinued for about the same reasons. Each clinic was owned and operated by the doctors who composed it. The income being divided on a percentage basis according to what each member produced the year before the organization was formed.

One man had to draw out of each group on account of failure of health and neither group could ever agree on their work afterward however dissatisfaction was arising beforehand because some thought others were not doing enough work to earn their part of the collections.

It is my opinion that a group can be run satisfactorily only by one or not more than two at most owning and controlling the institution the other members of the group being on a salary and possibly commission combined.

Another secretary explained the features that led to the failure of a group in his city as follows

About eighteen years ago a group was formed here. This group was made up of a surgeon, an eye, ear and nose specialist, an x-ray man, an internal medicine man and a dentist. This group continued as first organized and then began falling apart. There are no groups here now or in nearby towns.

The reason for falling to pieces of this group were many. In fact there was no good reason for such a group ever being organized, and every reason why it would die a natural death.

1. These men were not real specialists. They assumed that by dividing up the work they might prosper and draw the public patronage. In this territory we have the real thing in the way of specialists, men of outstanding worth. The people here know this fact and of course could not be drawn into such a clinic as these men here organized.

2. The layman could easily see that if he consulted one member of this group he would probably be sent to most of the other members for their opinion thus adding unnecessarily to the expense. There are too many men like myself in general practice who would not wish to refer patients to a local group but wish to take or send them to real specialists in the larger city where they can have the best of service. With graveled roads, ambulances, etc. patients and general practitioners alike naturally seek the best service.

Whatever the reasons for the groups falling to pieces in this territory (there were two clinics in this part of _____) they have long since gone out of existence and I would say that this is the best for the profession and the best for the laity. I believe that group practice has done more to bring the honorable members of the medical profession into disrepute than all other things. The layman would naturally come to distrust us all when some of us are banded together in a group. This group practice has done much to help the chiropractors by driving the laity over to them where the very thing I am speaking of is pointed out to the patients by these irregular practitioners.

The head of a group which has recently dissolved gave a vivid picture of the elements that led to dissolution.

The _____ Clinic was formed by the writer for the purpose of getting a group of qualified medical men who would assist me in carrying on a practice which had been built up to a point that I was unable to take care of it satisfactorily. There were too many problems for one small brain to solve.

My idea was that a group of men trained in different specialties would be beneficial to the individual patient and to the community and would make it possible for me to carry on a more satisfactory practice of medicine. The idea did not work out as I had anticipated. First the patients did not take to it kindly. They preferred to have the medical man of their own choice not one selected because of his qualifications to take care of them. Second when the men first came into the group they were willing to cooperate and worked satisfactorily but soon their egotism and selfishness got the best of them and they would no longer cooperate. Third each member of the group accepted their agreement of salaries and dividends with enthusiasm but after working a few years each one felt that they were not getting satisfactory compensation for the work that they were doing.

It was therefore impossible to satisfy the individual patient and the individual medical man. There was always dissension.

After twelve years of effort to carry on group practice I decided to break up the organization and did so on March 31 1932. All the men who were in the group at the time the organization was discontinued continue to occupy offices together and are now working together harmoniously all carrying on their individual practice satisfactorily.

After twelve years of experience with group practice it is my opinion that from the standpoint of the patient and the medical man connected with group practice it is unsatisfactory. I do not believe that our organization has proved an exception. I have talked to medical men connected with groups and find that the same condition exists with the other groups that I have contacted.

I would like to voice my opinion at this time, on the Majority Report of the Committee on the Cost of Medical Care. After twelve years of experience in a carefully organized and properly conducted group practice from both the business and ethical standpoint I believe that their plan is not workable from the standpoint of the individual patient or the physician. They will encounter the same difficulties that I have encountered in my group. The average American patient demands the privilege of selecting his own physician and the average American physician demands independence in conducting his medical practice. Neither the patient nor the physician will stand for dictation.

A secretary of a county medical society, after filling out the questionnaire for a defunct society, commented as follows:

The head of the clinic guaranteed each physician associated with the organization a certain amount annually understood to be about \$5 000 in some cases and less in others. After his own interest had been subtracted and the overhead charged off if any amount remained it was divided on a percentage basis. After three years of this arrangement the members of the clinic complained that the head was deriving more from the organizational activity than should be his and a reorganization was effected whereby the head of the clinic became an employee of the clinic as a whole. This did not last long. The younger members of the clinic soon found that they could not pay the amount guaranteed the head surgeon and founder of the organization. Another reorganization took effect. The founder of the clinic who had been well established in the community for years prior to his establishment of the clinic organization then left the organization and resumed a private practice. The younger members tried to carry on but after two or three years decided to dissolve the organization. All of them are now engaged in private practice in the community and the founder is dead.

The experience of another physician illustrates some additional points:

Some years ago I had in business with me three other men but I have discontinued the arrangement and at this time have only an anesthetist an associate who acts as my assistant, and a bookkeeper and I have confined my practice to surgery.

There are many reasons why group practice is desirable under certain circumstances but there are also a considerable number of disadvantages coincident with it. Each man in the group naturally inherits all the enemies as well as the friends of his associates. However the worst feature of group practice is the almost unavoidable tendency toward sending the patient the rounds of the different doctors so that he emerges with a rather elaborate examination and a fee commensurate with the time spent on him when he really intended to consult one man about a somewhat simple trouble.

These comments so thoroughly cover most of the weaknesses in group practice as to need little comment beyond calling attention to the manner in which they confirm a number of conclusions already indicated in reports of the operation of existing groups.

SUMMARY AND CONCLUSIONS

The outstanding conclusion from a summary of the analyses made of the various features is that there is no clearly defined or standardized type of group practice. Physicians are forming groups as they have always done, according to their personal friendships, financial advantages, scientific and professional ambitions and all the other motives that led Aristotle to call man a social animal. In a minority of instances it has been possible to assemble such a body of selected specialists and adequate scientific equipment as to constitute a fairly comprehensive medical unit, capable of offering a "complete medical service." That the great majority of groups do not have any such adequate representation of specialists is no reflection on the character of the work done or on the individuals composing the groups, but only on the exaggerated claims that have been made for group practice—claims that are largely based on the presumption that such comprehensive groups are typical.

There was a period of rapid formation of groups immediately following the war. Two reasons may account for this. A large number of physicians had served in the medical corps and been impressed with the value of organization. In the second place, the fame of the Mayo Clinic led to a belief that its success could be duplicated by a multitude of other groups. In reality, instead of this group forming a type to which all others approximated it has remained so unique as to be impossible of inclusion in any generalities regarding group practice. It would seem that the existence of the Mayo Clinic was also largely responsible for setting up a model which should have the comprehensive, all-sufficient character already considered.

Another possible contributing factor to accelerated growth in this period in cities of from 10,000 to 75,000 population may have been a lag between available laboratory and hospital facilities on the one hand and the recognition of the necessity of such facilities on the other. Pooling of medical resources undoubtedly did much to supply needed medical equipment and to improve local medical service.

It would appear that about 1920 a variety of limitations on further rapid expansion began to have an effect. It is true there was another peak of growth in the 'prosperity' years of

1928 and 1929. But although the industrial rise was higher, and both population and the number of physicians were greater, the number of groups organized during the three peak years was only a few more in the later period and, what is possibly more significant, the number of physicians entering these groups was 15 per cent less. This seems to indicate a return to earlier simpler and smaller forms of association and a tendency to abandon the attempt to build up the larger comprehensive type formerly envisioned as typical.

This slowing up in the rate of growth and the change in character may be due in part to changes in the environment and in part to some possibly unexpected developments within groups. There has been an extremely rapid growth in hospital and laboratory facilities during the last decade. A much larger percentage of individual physicians can now obtain access to these without the necessity of forming a group. A perhaps excessive development of specialization has also made available a wide choice of specialists for consultation in most cities. These developments reduce the incentive to form groups in order to obtain access to equipment and consultants.

Other developments that have appeared within the groups themselves have a tendency to limit the rapid extension of this form of practice. Given ample financial resources it is no difficult to assemble the physical equipment of an ideal group. But the figures showing the financial results of group practice do not seem to justify the conclusion that there is any such inherent economic advantage in such practice as to make the accumulation of the necessary funds for the purchase of extensive equipment inevitable. In fact there is considerable evidence to indicate that the existing equipment of many groups was purchased from previous individual earnings of those who formed them.

The analysis of the composition of group personnel suggests other difficulties in the formation of comprehensive groups. There is no such compelling economic force to produce the sort of organized specialization in medicine as is found in industry. Physicians are not only traditionally individualistic, but all professions have established a pattern of economic relations based on individual responsibility and personal management of economic dealings with patrons. There is a powerful resistance to any attempt to change that pattern into the one developed in industry, where the individual can toil at his occupation only by first finding a job and must then seek advancement through promotion within an established or organized hierarchy. The physician unlike the industrial worker, always has the alternative of individual practice and he prefers it to any form of association in his work. All specialization is highly developed there is no such grades of subordination such as exist in industrial organizations and are basic in most forms of organization. There is no "reserve army" of unemployed medical specialists that can be drawn on to fill the gaps in a group organization.

All relations between physicians, like those between physicians and patients, are intensely personal. Prestige and prestige are not the only, and probably not the most vital, qualities required to insure harmonious relations with colleagues and a lack of such harmony is destructive to service. Whether these reasons offer the best explanation for the failure of far more than a majority of groups to assemble an adequate and symmetrical body of specialists is a question that is impossible to answer.

Such other features as "physical equipment," "relations with patients," "methods of payment," "distribution of income among physicians," "variations and such slight, if any, correlation of these features as to indicate that their differences are determined largely by individual preference." All these features are auxiliaries to man's need of giving medical care and seldom are of any importance in determining these methods or even of affecting the cost of such care, unless they form a basis of lay domination of the medical practice. The tendency of lay writers to exaggerate these features seems to be a result of an attempt to show an analogy with industrial organization and development.

These features become of importance only when they tend to dominate the personal features. The latter are the basis of the medical profession.

may so dominate in some instances is suggested by the comments of the secretaries of county societies on the tendency of some groups to give an excessive number of laboratory tests. The comment of the Commission on Medical Education is also significant.¹⁰

Another tendency in medical practice is the emphasis placed upon mechanical devices. Great virtue is ascribed to laboratory and mechanical examinations of all kinds. These examinations are necessary in many instances as supplementary tools in determining diagnosis and in providing information not otherwise procurable. But the laboratory findings are valuable only in so far as they are correlated with the medical problem of a given patient. There has been a feeling that the development of laboratory methods tends to simplify diagnosis. The more scientific laboratory determinations become and the wider the field of their application the more thoroughly trained must the physician be to interpret correlate and utilize the findings of the laboratory in relation to the problem of the individual patient.

That financial relations with patients, when these involve insurance schemes or other forms of contract practice, may affect the character of medical service and the position of physicians is also quite evident.¹¹ There is some evidence that the existence of a heavy overhead may, in some instances, lead a group to adopt forms of contract practice which would otherwise be disapproved of by the majority of the members of the group.

The dominance of lay employees and especially of lay business managers, is apt to increase this tendency, which is also mentioned by some secretaries of county societies. So evident is this tendency that a committee of the Wisconsin Medical Society recently made the following recommendation.¹²

In such organizations as may employ a fiscal agent for the purposes of assessment and collection of fees our attention is called to the fact that such individuals frequently are the products of commercial schools and sometimes are financially interested in a showing of income over expenditures. Such a system lacking the immediate and personal supervision of a physician tends to result in fees exorbitant to particular individuals reflecting to the discredit not only of the group but of the entire profession. We earnestly recommend that this Society voice the principle that under the conditions cited some physician of the group be selected as the immediate adviser of the fiscal agent and be consulted in the matter of assessment and collection of all fees.

In the course of this study individual examples have been found in which it is claimed that advertising, offensive to the profession, instances of exorbitant and ill-balanced fees for certain services and special efforts to push such services as seemed most profitable, with little regard to their actual medical value, have resulted from lay financial management of groups. Of course, such abuses can be found in individual practice, but the fact that group organization under a lay business manager permits such practices to be initiated and conducted by a person not directly subject to professional discipline and not imbued with professional ideals suggests that the danger of such abuses is increased under such conditions.

Aside from the effects of these features, which are peculiar to group practice, there are far fewer fundamental differences between group and individual practice than most of the discussions of the two types seem to assume. There can be no different standards of judgment as to ethical or medical questions. The important differences among the groups are the same as those existing among individual practitioners, with possible reservations as to the tendency, already mentioned, of the group to accentuate the characteristics of its members.

Groups formed of congenial, able, conscientious members will increase all these qualities by association, and the opposite qualities will be equally aggravated when combined in a group. Individual physicians who have access to, and make all necessary use of available laboratory facilities and opportunities for consultation in cases in which there is a real need for these aids can give service in no important way differing from that given by even the well organized and equipped groups.

Association News

MEDICAL BROADCAST FOR THE WEEK

American Medical Association Health Talks

The American Medical Association broadcasts on Tuesday and Thursday from 9 15 to 9 20 a. m., Chicago daylight saving time, which is one hour faster than central standard time, over Station WBBM (770 kilocycles, or 389.4 meters). The subjects for the week are as follows:

June 6 The Ideal Food Label
June 8 We're All Much Alike.

There is also a fifteen minute talk sponsored by the Association on Saturday morning from 9 45 to 10 o'clock over Station WBBM.

The subject for the week is as follows:

June 10 Allergy in Childhood II

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ARIZONA

Society News—Dr. Eugene R. Lewis, Los Angeles, addressed the Cochise County Medical Society in Douglas, May 4, on otolaryngology.—Dr. Norman Kilbourne, Los Angeles, addressed the Pima County Medical Society, May 9, in Tucson, on internal hemorrhoids.

Health Program Planned.—A complete revision of the regulations of the Arizona State Board of Health will be undertaken in the immediate future. Although curtailment of appropriations will prevent complete expansion, it is planned to carry on a statewide educational campaign to teach the causes, care and avoidance of common diseases. In addition a system of weekly reports from practicing physicians will be inaugurated as a check-up on daily reports of contagious diseases made by them to the local health officer and efforts will be made to improve the reporting of venereal diseases in Arizona. A new death certificate will be issued, on which the length of residence in the state before death will be required. This insertion, with a report on the duration of the disease, will furnish statistics on the incidence of the disease arising in the state.

CALIFORNIA

New Laboratory Policy—At a meeting, April 22, the state board of health adopted the following general policies relating to service provided by the state bacteriologic laboratory:

1. No specimens will be received from cities or counties having no approved public health laboratory.
2. Blood specimens to be examined as a check on treatment will not be received except for indigent patients and from communities not excluded by the first ruling.
3. Blood specimens will be received for purposes of diagnosis only from communities not excluded by the first paragraph.
4. Name and postoffice address of every Wassermann patient must accompany the sample and the question as to indigency must be answered.
5. The chief of the laboratory is authorized to mail a notification to each patient advising him that no charge is made by the state for the examination.
6. Blood specimens will be accepted from all state institutions and county hospitals without reservation other than that county hospitals receiving pay patients may send specimens only from patients who do not pay so certifying on the form accompanying the specimens.
7. The chief of the bureau of laboratories is authorized to refuse service to physicians who do not comply with these requirements.

CONNECTICUT

Anniversary of Mental Hygiene Movement—The twenty-fifth anniversary of the establishment of the mental hygiene movement in the United States was observed in Sprague Hall, New Haven, May 6, by the Connecticut Society for Mental Hygiene, the National Committee for Mental Hygiene and Yale University. The mental hygiene movement, now nationally organized, began with the founding of the Connecticut society by Mr. Clifford W. Beers, May 6, 1908. Among the early sponsors of the movement were Dr. William H. Welch, James Rowland Angell, LL.D., Russell H. Chittenden,

Henry van Dyke, Anson Phelps Stokes, Jane Addams, Julia Lathrop, Major Henry L. Higginson, George Wharton Pepper, Jacob Gould Schurman, William H. P. Faunce, Melville E. Stone, Dr. Charles Maché Campbell, Dr. Adolf Meyer, and Wilbur L. Cross, now governor of Connecticut. The first international congress on mental hygiene was held in Washington, D. C., in 1930, attended by delegates from more than fifty countries. The second will take place in Paris in 1935. The American Foundation for Mental Hygiene was created in 1928 to serve as custodian and administrator of gifts and bequests for agencies or work in any part of the field. The program celebrating the event in New Haven included the following:

Governor Cross, The Place in Literature of 'A Mind That Found Itself'—The Book That Started a Movement

James R. Angell, president Yale University Mental Hygiene in Colleges and Universities.

Charles Edward A. Winslow, DPH, professor of public health, Yale University School of Medicine, Growth of the Mental Hygiene Movement During the Past Twenty-Five Years and the Unique Work of Its Founder

Mr. Beers, Glimpses of the Development of the Movement

At the morning session, "Mental Hygiene in Education" was discussed by the following: Mark A. May, Ph.D., professor of educational psychology, Yale University; William J. Cooper, commissioner of education, Washington, D. C.; Vivian T. Thayer, Ph.D., educational director, ethical culture schools, New York; and Dr. Marion E. Kenworthy, director department of mental hygiene, New York School of Social Work, New York. Mr. Beers is the founder and secretary of the national committee, organized in 1909, the American Foundation, and of the International Foundation for Mental Hygiene, established in 1931. He is general secretary of the International Committee for Mental Hygiene, which he founded in 1930. At the recent observance, a volume of tributes, collected by Dr. Welch, was presented to him.

DISTRICT OF COLUMBIA

Personal—The appointment of Major James Stevens Simmons as a member of the National Board of Medical Examiners has been approved. Dr. Simmons is director of laboratories and of the department of preventive medicine in the Army Medical School. He succeeds Major Paul E. McNabb, who has been assigned to duty in the Philippines.

Graduate Clinics—The first graduate clinics of the George Washington University School of Medicine will be conducted in Washington, June 5-7. All the first day will be devoted to surgical and medical subjects at the Gallinger Municipal Hospital. The second day ward rounds and laboratory demonstrations will be given at the medical school while the third will be devoted to special clinics at various hospitals. Demonstrations and clinical material in psychiatry, designed particularly for the general practitioner, will also be presented on the last day. No fees will be charged. It is hoped to make these clinics an annual event.

University News—Dr. William H. Howell, Baltimore, addressed the Smith-Reed-Russell Society of George Washington University School of Medicine, April 6, on "Recollections of a Physiologist During the Past Half Century."—Owen Stanley Gibbs, M.B., professor of physiology and pharmacology, University of Georgia School of Medicine, has been appointed professor of physiology at Georgetown University School of Medicine.—Dr. Eliot R. Clark, Philadelphia, addressed the faculty and students of the George Washington University School of Medicine, April 29, on "Spontaneous Activity of Capillaries."

FLORIDA

Bills Introduced—H. 1161, to amend the pharmacy practice act, proposes that persons other than licensed pharmacists may operate and conduct pharmacies but that no one other than a licensed pharmacist can sell, compound or dispense drugs or medicines, except proprietary and patent medicines in the original packages. The bill proposes, too, that every prescription compounded and dispensed shall bear a label on the bottle or other container, stating the license number of the registered pharmacist who compounded it. H. 1197 and S. 657 propose to establish throughout the state a system of dispensaries for dispensing and distributing for medical purposes narcotic drugs and all potable solutions containing ethyl alcohol except vinous and malt solutions containing not in excess of 3.2 per cent. Narcotics are to be dispensed only on the written prescription of a physician, dentist or veterinarian.

State Medical Meeting and Election—Dr. William M. Rowlett, Tampa, was installed as president of the Florida Medical Association at its sixtieth annual meeting, in Hollywood May 2-4, succeeding Dr. Gerry R. Holden, Jacksonville. Dr. Homer L. Pearson, Jr., Miami, was named president-elect.

Vice presidents are Drs. James Ralston Wells, Daytona Beach, George C. Tillman, Gainesville, and Henry J. Peavey, Jr., Fort Lauderdale, and Dr. Shaler Richardson, Jacksonville, is the secretary. Jacksonville was selected as the place for the annual meeting in 1934. The scientific program included the following physicians as speakers:

Walter E. Dandy, Baltimore, Brain Tumors, Their Diagnosis and Treatment.

Henry E. Palmer, Tallahassee, Poisonous Effect of the Nuts of the Tung Oil Tree if Eaten by Man.

Joseph S. Spoto, Tampa, Treatment of Hemophilia with Ovarian Extract.

Alan Brown, Jacksonville, Lymphopathia Venerea.

Herbert E. White, St. Augustine, Appendicitis with Its Increasing Mortality.

Roy J. Holmes and Milton M. Coplan, Miami, Review of Some Urinary Anomalies and Pathologic Conditions Producing Symptoms of Especial Interest to the General Practitioner.

George M. Dawson, West Palm Beach, Carcinoma of the Colon.

James H. Fellows, Pensacola, Cerebral Injuries of the Newly Born.

Homer L. Pearson, Jr., Miami, Placenta Praevia.

Robert B. Harkness, Lake City, Granuloma Inguinale.

Joseph Halton, Sarasota, Observation of Five Hundred Fractures.

Wilfred M. Shaw, Jacksonville, Fractures at the Ankle and Wrist Joints.

George E. W. Hardy, Jr., Tampa, Fractures of the Cervical Spine Below the Atlas and Axis with Report of Two Cases.

Warren W. Quillian, Coral Gables, Use of Unsweetened Evaporated Milk in Infant Feeding.

Joseph W. Taylor, Tampa, Unilateral Exophthalmos.

Charles F. Roche, Miami Beach, and Thomas Duckett Jones, Boston, Heart Disease of the Rheumatic Type.

Turner Z. Cason, Jacksonville, Hypothyroidism in Adolescent Girls with Particular Reference to Social Delinquency.

Henry C. Dozier, Ocala, Problems of Medicine.

Henry Hanson, Jacksonville, A State Health Department's Service to the Medical Profession.

ILLINOIS

Bill Introduced—S. 642, to amend the occupational disease act, proposes to require employers, using any process of manufacture or labor in which silicon dioxide is employed, to remove the dust created in such process by either ventilating or exhaust devices.

Lectures in Pediatrics—During the summer and fall a one day lecture course in pediatrics will be conducted in eleven districts of Illinois, under the auspices of the American Academy of Pediatrics and the educational committee of the Illinois State Medical Society. The following cities have been tentatively selected as the centers: Chicago, Rockford, Rock Island, La Salle, Peoria, Springfield, Quincy, Champaign, East St. Louis, Effingham and Benton. Subjects to be covered by the course include care of the new born, care and feeding of infants, preventive pediatrics, behavior problems and discipline in children, and general treatment of the sick child. The five pediatricians who have been selected to organize groups of teachers are Drs. Isaac A. Abt, Julius H. Hess, Joseph Brenne-mann, Clifford G. Grulee and Robert A. Black, all of Chicago.

Society News—The St. Clair County Medical Society was addressed in East St. Louis, May 4, by Dr. William F. Hardy, St. Louis, on ophthalmologic problems from the point of view of general practice and in Mascoutah, May 3 by Dr. Grandison D. Royston, St. Louis, on high points in obstetric care.—Dr. Harvey J. Howard, St. Louis, discussed "Aviation Medicine and Its Contribution to General and Special Medicine" before the Sangamon County Medical Society, Springfield, April 6.—Dr. Richard S. Weiss, St. Louis, addressed the Madison County Medical Society, April 7, at Collinsville, on "The Precancerous Dermatoses."—The Lake County Medical Society was addressed, May 9, by Dr. Robert H. Herbst, Chicago, whose subject was "Transurethral Electro-resection of the Prostate Gland."

Chicago

Search for Precocious Students—Northwestern University's attempt to meet the needs of precocious students between the ages of 13 and 15 will be extended next year, it was announced recently. The scholarship of the four boys and two girls admitted in September, 1932, is considerably above that of the freshman average. The students are under the supervision of a faculty committee specially interested in the training of precocious students. High school principals are now being asked to send to the university names of likely candidates for a second group of precocious students. The university will select those who manifest unusual potentialities for distinguished services in one of the arts, sciences or professions. By precocious, it was pointed out, is implied an intelligence quotient of more than 130 or unusually early mental development (THE JOURNAL, Feb. 27, 1932, p. 742).

Dr. Jordan to Retire as Chairman—William H. Taliaferro, Ph.D., associate dean of the Division of the Biological Sciences, University of Chicago, has been appointed chairman of the department of hygiene and bacteriology to succeed Edwin

O Jordan Ph D, who retires October 1, after forty-one years association with the university. Dr Talaferro came to the University of Chicago in 1924 from Johns Hopkins, where he had been a member of the teaching staff since 1918. He has been professor of parasitology since 1927 and associate dean since 1931. He is president of the American Society of Parasitologists. Dr Jordan a native of Maine and a graduate of Massachusetts Institute of Technology, came to the University of Chicago as associate in anatomy in 1892. He was appointed assistant professor of bacteriology in 1895, associate professor in 1900, and professor in 1907. When the department of hygiene and bacteriology was set up in 1914, Dr Jordan was appointed chairman. He is editor of the *Journal of Preventive Medicine* and joint editor of the *Journal of Infectious Diseases*. The Andrew McLeish Distinguished Professorship was awarded to Dr Jordan in 1932. He is a former president of the Society of American Bacteriologists and the American Epidemiological Society. As professor emeritus he will offer some graduate courses and will continue his research in the department.

LOUISIANA

New Cancer Clinic—A modern clinic for the treatment and prevention of cancer will be established at Charity Hospital New Orleans, it was recently announced. Adequate facilities for the study of the nature, cause and cure of the disease will be provided. According to the report, this clinic, the first one of its kind in this section of the country, was to have been ready for operation the latter part of May.

Fellowships Awarded—The Gorgas Medical Society of New Orleans awarded honorary fellowships to Drs Arthur Vidrine for his work in surgery, Joseph Rigney D'Aunoy for his work on electrocardiography and Richard Ashman, Ph D, for achievement in research, with special ceremonies at Louisiana University Medical Center April 7. The awards are made to those who have distinguished themselves in medical science and research," it was reported. Dr Vidrine is dean of the medical center. Dr D'Aunoy, professor of pathology and bacteriology and executive secretary of the center, and Dr Ashman, professor of physiology. These fellowships are the first to be awarded by this society, which was organized last year by Dr Clyde Brooks professor of pharmacology and experimental therapeutics at the center.

MASSACHUSETTS

Hospital Reunion—Peter Bent Brigham Hospital, Boston held its annual reunion May 4-6. On the scientific program were the following physicians:

Henry A. Christian the address of welcome.
Tom D. Spies, Cleveland Recent Studies of Pellagra
Cecil K. Drinker Experimental Lymphatic Obstruction in the Dog
George R. Herrmann, Galveston, Texas Practical Augmentation of Diuresis by Combinations of Antihines and Heavy Metals
Eric P. Stone, Providence R. I. Vegetative Nerve Disturbance of the Urinary Bladder
Walter B. Cannon Recent Studies on Chemical Transmission of Nerve Impulses
Reginald Fitz Cause of Death Among Recent Graduates in the Harvard Medical School Certain Needs for a Well Organized Department of Student Health in the Process of Medical Education
Joseph T. Wearn Cleveland Circulation of the Heart
Emil Goetsch Brooklyn Adrenal Factor in Reactions to Thyroidectomy
Ashley W. Oughterson New Haven Phases of Studies of the Sympathetic Nervous System
John F. Fulton Jr. New Haven Spastic Primates
Richard M. McKean, Detroit Clinical Application of the Micro-Internal Glucose Tolerance Test
Louis G. Herrmann Cincinnati Experimental and Clinical Studies on Pulmonary Fat Embolism
Vincent D. Vermooten New Haven Postural Drainage in the Treatment of Acute Pyelitis
Courtney C. Bishop New York Repair of Kidney Wounds with Ribbon Gut
John M. Fallon Worcester Trichiniasis as a Simulant of Intra Abdominal Surgical Disease
William deG. Mahoney New York, Anterior Lobe of the Hypophysis in Carbohydrate Metabolism

MICHIGAN

Bills Introduced—S 242 proposes to authorize licensed physicians to prescribe such amounts of intoxicating liquors as they deem necessary to supply the medicinal needs of their patients. H 620 proposes to repeal the laws regulating the possession and distribution of narcotic drugs and to enact the uniform narcotic drug act. H 656 proposes to accord to hospitals maintained in whole or in part by private charity or operated by any municipal or county board, which treats persons injured through the fault of other persons liens on all judgments, claims, compromises or settlements accruing to the injured persons by reason of their injuries.

Society News—Dr Henry E. Michelson, Minneapolis addressed a joint meeting of the Wayne County Medical Society and the Detroit Dermatological Society, April 18 on cancer

of the skin.—Clinical conferences on tuberculosis were held at the Detroit Tuberculosis Sanatorium, April 18 and April 20, by Drs Willard B. Howes and Earl S. Bullock. A talk on 'History Taking and Physical Examination in Tuberculosis' and a clinical demonstration of physical signs in tuberculosis were presented.—Henry F. Vaughan, Dr P. H., addressed a joint meeting of the Wayne County Medical Society and the East Side Medical Society, May 2, on "Medical Participation in Public Health".—Dr Carl E. Badgley, Ann Arbor, conducted a clinic and spoke on surgery of the knee joint before the Kalamazoo Academy of Medicine, April 18.—Dr Ward F. Seeley, Detroit, addressed the Calhoun County Medical Society, Battle Creek, May 2, on "Symptomatology and Treatment of Some of the Injuries Resulting from Childbirth".—A symposium on tuberculosis was presented before the West Side Medical Society, Detroit, April 6, speakers were Drs. Henry D. Chadwick, Richard H. Morgan and Edwards J. O'Brien.—At a meeting of the Highland Park Physicians Club, April 6, Dr Charles L. Brown, Ann Arbor, spoke on "Peptic Ulcer with Special Reference to Gastric Physiology and Diagnosis".

MISSOURI

Annual Spring Clinics—The St. Joseph Clinical Society conducted its annual spring clinics, April 19-20. Sessions were held in the Hotel Robidoux, Missouri Methodist Hospital and St. Joseph's Hospital, St. Joseph. Guest speakers on the program included the following physicians:

Philip C. Jeans professor of pediatrics State University of Iowa College of Medicine, Iowa City Early Diagnosis of Tuberculosis in Children.
William P. Wherry professor of otorhinolaryngology University of Nebraska College of Medicine Effect of Recent Research on the Control of Parasual Sinusitis.
John R. Caulk professor of clinical genito-urinary surgery Washington University School of Medicine, St. Louis, a banquet address on Cautery Punch Operation for the Removal of Prostatic Obstruction.
Earl C. Padgett assistant professor of surgery University of Kansas School of Medicine Kansas City, Early and Late Treatment of Burns.
Logan Clendening professor of clinical medicine, University of Kansas School of Medicine Kansas City a banquet address on Treatment of Diabetic Coma.
Leroy A. Calkins professor of gynecology and obstetrics University of Kansas School of Medicine, Treatment of Carcinoma of the Cervix—Technic and Results.
Earl A. Menninger director Menninger Clinic, Topeka Surgery and the Neurotic Patient.
Ensley T. Johnson pathologist, St. Joseph Hospital Kansas City Newer Forms of Scientific Research.
Norman M. Keith Mayo Clinic, Rochester Minn. banquet address, Diffuse Arterial Disease with Hypertension.
Alexis F. Hartmann associate professor of pediatrics Washington University School of Medicine, St. Louis banquet address Clinical Applications of Recently Acquired Knowledge Concerning Dehydration Edema and Chemical Changes in the Body.

NEW JERSEY

State Board Prosecutions—The Board of Medical Examiners of New Jersey has recently reported the following convictions for violations of the medical practice act among others:

Chester Vliet, Ashbury Park, a chiropractor who exceeded his license by giving electric treatments paid the penalty for practicing medicine without a license.
August Miller, Millville a chiropractor, Scott H. Rosser, Bridgeton an osteopath and Ellsworth Pierce, Bridgeton a naturopath were found guilty of practicing without licenses by the judge of the Cumberland County Court of Common Pleas.
Jacob H. Schmitter, Paterson found guilty of practicing medicine without a license, required his patients to become members of a homeopathic society incorporated in the state in 1897 the charter of which he had in his possession. He then treated them with drugs.
Hester Armstrong, Roselle Park pleaded guilty in the Linden District Court to a charge of practicing medicine without a license. She is said to have prescribed drugs some of which she manufactured.

State Medical Meeting at Atlantic City—The one hundred and sixty-seventh annual meeting of the Medical Society of New Jersey will be held in Atlantic City, June 6-9, at Haddon Hall. Sections will meet in the morning and general sessions will be held in the afternoons. The first general session will be devoted to a symposium on urology presented by Drs. Alexander Randall, Philadelphia, Joseph F. McCarthy, New York, Thomas C. Stellwagen Jr., Philadelphia, Stanley R. Woodruff, Jersey City, and William J. Carrington, Atlantic City. Guest speakers on other programs will include:

Dr. David Riesman, Philadelphia, Disease of the Coronary Arteries.
Dr. Albert S. Hyman, New York, Electrocardiographic Work.
Dr. Philip F. Williams, Philadelphia Avoidable Factors in Maternal Mortality.
Dr. Robert A. Cooke, New York, Causes and Management of Asthma in Children.
Dr. Edward T. Donovan, New York, Abdominal Surgery in Infants and Children.
Dr. John Mitchell Brush, New York, Initial Stabilization of the Juvenile Diabetic.
Dr. Meredith F. Campbell, New York, Surgical Diseases of the Upper Urinary Tract in Infants and Children.
Dr. Harry E. Kleinschmidt, New York, Tuberculin Testing of Children.
Edgar B. Burchell, New York, Anatomy of the Temporal Bone and Its Variations.

A new feature of the annual meeting this year will be an exhibit of fine arts and hobbies of members. Members of the physicians' families have also been invited to display their handiwork.

NEW YORK

Health at Utica—Telegraphic reports to the U S Department of Commerce from eighty-five cities with a total population of 37 million, for the week ended May 20, indicate that the highest mortality rate (18.2) appears for Utica, and that the rate for the group of cities as a whole is 10.6. The mortality rate for Utica for the corresponding period last year was 11.7, and for the group of cities, 11.4. The annual rate for eighty-five cities for the twenty weeks of 1933 was 11.8 as against a rate of 12.4 for the corresponding period of the previous year. Caution should be used in the interpretation of weekly figures, as they fluctuate widely. The fact that some cities are hospital centers for large areas outside the city limits or that they have a large Negro population may tend to increase the death rate.

Society News—Dr William F MacFee, New York, addressed the Utica Academy of Medicine March 16 on "Prevention and Treatment of Postoperative Shock."—Henry F Vaughan, Dr P H, Detroit, addressed the Rochester Tuberculosis and Health Association and St. Mary's Hospital Clinical Society, Rochester, March 7-8 on public health and the economic depression.—A conference of health officers of Cavuga, Cortland, Onondaga, Seneca Oswego and Wayne counties was held in Syracuse, April 21. The principal topic discussed was scarlet fever. Among those who spoke were Drs George H Ramsey of the state department of health, Gregory D Mahar and Orren D Chapman, Syracuse, and Robert Knight, Seneca Falls.—Dr I Newton Kugelmass, New York, addressed the Medical Society of the County of Albany, April 19, on 'Hemorrhages in the New-Born.' Dr Kugelmass also addressed students of Albany Medical College on "Hemorrhagic Diseases of Infancy and Childhood."

New York City

Society News—Drs Frank H Lahey and Elliott P Joslin, Boston addressed the Medical Society of the County of Kings April 18, on "Carcinoma of the Colon and Rectum" and "Lessons from Diabetic Children for Diabetic Adults," respectively. A motion picture showing the mechanism of the heart beat in electrocardiography was also shown. Dr Henry M Moses presented the last of the society's Friday afternoon lectures May 5, on 'Management of Old Age Conditions.'—Dr John J Moorhead addressed the Medical Society of the County of Queens, May 5, on 'Problems in Traumatic Surgery' and Dr Robert T Frank April 21 on 'Recognition and Treatment of Infections of the Female Genital Tract.'—Drs Martin E Rehfuess, Philadelphia and Asher Winkelstein addressed the Society for the Advancement of Gastro-Enterology April 26, on "Smooth Muscle Function of the Stomach" and 'A New Therapy of Peptic Ulcer Continuous Alkalinized Milk Drip into the Stomach' respectively. Among others Dr Walter B Cannon Boston discussed the papers.—Dr Emil Goetsch addressed the New York Surgical Society May 8 on 'Hvgroma Cysticum Colli: An Analysis of Ten Cases.'—The New York Neurological Society met jointly with the section of neurology and psychiatry of the New York Academy of Medicine May 2. Dr Edwin M Deery presented a paper on 'Histological Features of Glioblastoma Multiforme.'—A symposium on bone tumors was presented before the Bronx County Medical Society, May 17 by Drs James Ewing, William B Coley and Ralph E. Herendeen.

OHIO

Cincinnati Alumni Reunion—The annual reunion of graduates of the University of Cincinnati School of Medicine will be held Friday June 9. The scientific program will consist of demonstrations of the work of the cancer clinic and the vascular clinic. Arrangements have been made for golf at the Maketawah Country Club. The annual banquet will be at the Hotel Gibson with Raymond Walters, M A, president of the University of Cincinnati. Dr Richard Austin Mary M Emery professor of pathology and Dr Mont R Reid Christian R Holmes professor of surgery in the college of medicine, as the speakers.

Society News—Dr Foster Kennedy, New York, addressed the Cincinnati Academy of Medicine, May 22 on epilepsy.—Dr Halford F Conwell addressed the Cincinnati Obstetrical Society May 11 on 'Spasms of the Uterus.'—Dr Paul C. Langan presented a paper on 'Lung Pathology in Relation to Industrial Compensation' before the Summit County

Medical Society, Akron May 2.—Dr John F Beachler, Piqua, addressed the Miami County Medical Society April 14, on treatment of acute intestinal obstruction.—Dr Victor W Fischbach Cincinnati, among others, addressed the Adams County Medical Society West Union April 26, on 'Common Colds and Catarrhal Ailments.'—Members of the Toledo Academy of Medicine visited clinics especially arranged by the department of postgraduate medicine of the University of Michigan, May 17, at the University of Michigan Hospital, Ann Arbor. Dr Albert E Russell of the U S Bureau of Mines Washington, D C addressed the academy at its meeting May 5, on 'Occupation and Respiratory Diseases.'—Dr Willis C Campbell Memphis Tenn, addressed the Cleveland Academy of Medicine, May 19, on 'The Fracture Problem.' Dr Campbell also held a clinic on fractures at St. Luke's Hospital in the afternoon.—Dr George W Crile, Cleveland, addressed the Muskingum County Academy of Medicine Zanesville, May 3 on 'Peptic Ulcers and Exophthalmic Goiter' and on "Neurocirculatory Asthenia and Diabetes."—Dr Karl D Figley, Toledo addressed the Columbus Academy of Medicine, May 8, on diagnosis and treatment of hay fever.

PENNSYLVANIA

Society News—Speakers at the meeting of the Allegheny County Medical Society, Pittsburgh, May 16, were Drs John W Shurer on "Goiter and Neurocirculatory Asthenia," Harry I Miller, 'Malignant Hypertension,' Susan R Offutt, 'Female Sex Hormones—Therapeutics' and Robert M Entwistle, "Complications of Acute Appendicitis." The graduating class of the University of Pittsburgh School of Medicine and interns finishing their service in Allegheny County hospitals were guests at this meeting.—The annual meeting of the Ninth Councilor District of the Medical Society of the State of Pennsylvania was held at State Teachers College, Slippery Rock, May 18. Among the speakers were Drs John D Garvin, Pittsburgh, on 'Changing Concepts in the Treatment of Organic Indigestion' and Arthur P Keegan, Philadelphia, 'Past, Present and Future Concepts of Malignancy.'

Philadelphia

County Society Programs—A child health program was presented before the Philadelphia County Medical Society, May 24 in cooperation with the Philadelphia Child Health Association. Dr John Lovett Morse, Boston spoke on 'The Requirements for a Minimum Diet' and Dr Joseph Stokes Jr, on 'Application of Minimum Nutritional Requirements to the Family Diet.' The society's program, May 17, was devoted to reports of thirteen subcommittees of the committee on medical economics.—Senior students of the University of Pennsylvania School of Medicine, Jefferson Medical College, Temple University School of Medicine and the Woman's Medical College of Pennsylvania were guests of the Philadelphia County Medical Society at a meeting April 27. Drs George Morris Piersol spoke on 'The Relation of the Physician to Medical Organization' Judson Daland 'Suggestions to Senior Medical Students Regarding Their Future in Medicine' and Francis Ashley Faught, 'The Recent Trend in Medical Economics.'

RHODE ISLAND

Society News—At the meeting of the Rhode Island Ophthalmological and Otolological Society in Providence April 27, the speakers were Drs Jay N Fishbein on 'Rhinological Treatment of Asthma', Jeffrey J Walsh, 'Sinus Disease in Children' and Banice Femberg, 'Relationship of Gastric and Pulmonary Symptomatology to Sinus Disease in Children.'—Drs David R Brodsky, Craig S Houston and John F Murphy, Providence, discussed 'Trichomonas Vaginalis Infection' and Dr Anthony Bassler, New York, "Clinical Significance of Pancreatic Disorders," at the meeting of the Providence Medical Association May 1.—Dr Soma Weiss, Boston, spoke on "Cerebral Arteriosclerosis" at the State Hospital for Mental Diseases Howard, April 17 and Dr Chester S Keefer, Boston, May 15, on 'Deficiency Diseases in Adults.'

TENNESSEE

Duplicate Diploma—The University of Tennessee College of Medicine Memphis, reports the issuance of a duplicate diploma to Dr Vaughan C Price, McPherson, Kan, May 1. Dr Vaughan lost his diploma in a fire that recently destroyed the building in which his office was located. He was graduated in 1929.

Society News—Dr Joe E Hall, Greenback, addressed the Blount County Medical Society Maryville, May 4 on "Management of Normal Labor."—Drs Jay Arthur Myers, Min-

neapolis, and Hollis Johnson, Nashville, discussed tuberculosis at a meeting of the Gibson County Medical Society, Trenton in March—Dr Charles Sidney Burwell, Nashville, addressed the Sullivan-Johnson Counties Medical Society, Kingsport, April 4 on chronic heart disease—At a meeting of the Memphis and Shelby County Medical Society April 4, Dr Harry C Schmeisser, Memphis discussed Tuberculous Endophlebitis, and Edgar D Rose, dean University of Tennessee School of Dentistry, Memphis, 'Dental Infections and Their Relation to Systemic Disease.'—Dr Edgar L Grubb addressed the Knox County Medical Society, Knoxville, May 2, on "Bronchoscopy in Pulmonary Disease."—Drs James C. Fly, Kingston and Rolland F Regester, Rockwood, addressed the Roane County Medical Society Harriman, April 19, on 'Tuberculosis in Tennessee' and Manipulation as a Therapeutic Measure," respectively—At a meeting of the McMinn County Medical Society Athens, April 20 Drs Howard P Hewitt and Talbert C Crowell, Chattanooga discussed 'Modern Practice of Obstetrics and Allergic Diseases,' respectively—Dr Worcester A Bryan Nashville, lectured on fractures at a meeting of the Robertson County Medical Society, Springfield April 18

WASHINGTON

Society News—Drs Frank J. Glancy and Cline F. Davidson were speakers before the King County Medical Society Seattle, May 1, on Neuropsychiatry Applied to Urology and Sex and Internal Secretions respectively. At the meeting, May 15 Dr James M. Bowers Seattle presented 'A Clinical Study of Gastric Ulcers in Various Locations' and Walter Kelton Seattle a discussion of 'Medicolegal Racketeering'—Dr Alexander H. Peacock Seattle, president Washington State Medical Association addressed the Stevens County Medical Society Colville, April 25 on plans for care of the unemployed sick and Dr Herbert E. Coe Seattle on the formation of a cooperative association of private and governmental hospitals

WEST VIRGINIA

Bill Introduced—H. 104 X proposes to authorize cities and incorporated towns among other things, to establish and maintain municipal hospitals

WYOMING

Joint Society Meeting—Members of the Yellowstone Valley Medical Society were the guests of the Sheridan County Medical Society and the medical officers of the new Veterans' Administration Hospital Sheridan March 24. Addresses were presented by Drs. Andrew F. O'Connor, on "Paresis and Other Forms of Neurosyphilis," Charles H. Burdick, "Forms and Stages of Dementia Praecox," Joe H. Price, Jr. "Type Cases of Mania and Mental Depression" and Thomas G. McLin, "Encephalitis Lethargica with Mental Symptoms"

GENERAL

American Proctologic Society—The thirty-fourth annual session of the American Proctologic Society will be held in Chicago, June 12-13, at the Stevens Hotel, under the presidency of Dr. Curtice Rosser, Dallas, Texas. The scientific program includes the following speakers:

Dr. Jacob A. Barger, Rochester, Minn. Colonic Function
Arthur I. Kendall, Ph.D. Chicago. Intestinal Flora
Dr. Homer H. Wheeler, Indianapolis. Anesthetics in Postoperative Treatment of Rectal Diseases
Dr. Martin J. Synnott, Montclair, N. J. Diverticulitis
Dr. Martin S. Kleckner, Allentown, Pa. Coccygodynia—Present Day Interpretation and Treatment
Dr. Curtis C. Mechlign, Pittsburgh. Comments on Pectinosis
Dr. Harry E. Bacon, Philadelphia. The Gruskun Test for Cancer

Health Education Conference—The American Child Health Association will conduct its seventh health education conference in Ann Arbor, June 20-24, at the invitation of the University of Michigan. Discussions will center on practical problems in the school health program in teacher, secondary and elementary education. Objectives of the conference are to:

Chart significant trends and characteristics in school health programs
Clarify problems of basic significance which apparently retard the future growth of programs
Formulate through group thinking sound principles and unified policies of practical constructive value.

Further information may be obtained from Miss Anne Whitney, director educational service, American Child Health Association, 450 Seventh Avenue, New York.

Medical History Meeting—Dr. James B. Herrick, Chicago, was elected president of the American Association of the History of Medicine at the annual meeting in Washington D. C., May 8, succeeding Dr. Gerald B. Webb, Colorado

Springs, Colo. Drs. Charles N. B. Camac, New York, and William S. Middleton, Madison, Wis., were elected vice presidents and Dr. Edward J. G. Beardsley, Philadelphia secretary. The program included addresses by Drs. William G. Leaman, Jr., Philadelphia on "Tobias Smollett, M.D. Physician and Novelist", Maude E. L. Abbott, Montreal, "Evolution of Medical Journalism in Canada", Henry E. Sigerist, Baltimore, "Medical Literature of the Middle Ages," and Logan Clendenning, Kansas City, "The Dear Little Boy (Edward Wortley Montagu, Jr.)"

Conference on the Hard of Hearing—The fourteenth annual meeting of the American Federation of Organizations for the Hard of Hearing will be held in Chicago June 19-22, with headquarters at the Lake Shore Athletic Club. Among speakers listed on a tentative program are:

Dr. Wendell C. Phillips, New York. Relation of the Activities of the League to Health
Dr. Edmund F. Fowler, New York. Variations in the Hearing with Otosclerosis. Etiology, Prognosis and Treatment
Dr. Horace Newhart, Minneapolis. The Hard of Hearing School Teacher
Dr. Gordon Berry, Worcester, Mass., How I Behave as I Grow Hard of Hearing
Allan Winter Rowe, Ph.D. Boston. Incidence of Hearing Failure in Children of Rural Communities
Dr. George E. Shambaugh, Jr., Chicago. Progressive Deafness in Identical Twins.

Dr. Morris Fishbein, Chicago, editor of THE JOURNAL will participate in a publicity clinic, Tuesday afternoon, June 20. The annual banquet will be held Thursday evening, with Jane Addams of Hull House and Dr. Wendell Phillips as speakers.

Conference on Rheumatic Diseases—The American Committee for the Control of Rheumatism will sponsor its second conference on rheumatic diseases at the Hotel Schroeder, Milwaukee June 12. Abstracts of papers will be presented by the following physicians:

Chester S. Keefer and Walter K. Myers, Boston. Incidence and Pathogenesis of Degenerative Arthritis
Ralph K. Ghormley, Rochester, Minn. Joint Tissue Changes in Chronic Atrophic (rheumatoid) Arthritis with Special Reference to the Early Stages
Walter Bauer, Boston. Physiology of Normal Joints as Related to Chronic Atrophic (rheumatoid) Arthritis
Martin H. Dawson and Ralph H. Boots, New York. Studies in Chronic Arthritis (bacteriology, agglutination and sedimentation tests and vaccine therapy)
Andrew A. Fletcher, Toronto. Nutritional Aspects of Chronic Arthritis
John A. Key, St. Louis. Contusions of Cartilage as an Etiological Factor in Chronic Arthritis
William J. Kerr, San Francisco. The Common Denominator in Most Methods of Treatment of Chronic Arthritis
George R. Minot, Boston. General Aspects of the Treatment of Chronic Arthritis
Philip S. Hench, Rochester. The Analgesic Effect of Hepatitis and Jaundice (from cinchophen and other causes) in Arthritis Fibrositis and Sciatic Pain. Preliminary Report.

Bequests and Donations—The following bequests and donations have recently been announced:

Winona General Hospital, Winona, Minn. the bulk of a \$200,000 estate by the will of the late John Dietze, president of the hospital board since 1920.
Norwegian Hospital, Brooklyn \$2,500 by the will of Mrs. Emma C. Normann.
Montefiore and Mount Sinai hospitals, New York \$5,000 each under the will of the late Elias Kemper.
Murray Hill Sanitarium and Mount Sinai Hospital \$10,000 each under the will of the late Selma Rossmann.
Somerset Hospital, Somerville, N. J. \$10,000 by the will of William Morgan Savin.
Shrine Hospital for Crippled Children, Minneapolis \$10,000 by the late Mr. E. A. Gowan.
Memorial Hospital, Pawtucket, R. I. \$10,000 given by Mrs. Kenneth F. Wood in memory of her parents.
St. Luke's Hospital, Davenport, Iowa, \$1,000 under the will of the late Mrs. Lena Anken.
Manhattan Eye, Ear and Throat Hospital, New York \$5,000 under the will of the late Norman Henderson.
Montefiore and Mount Sinai hospitals, New York \$1,000 each by the will of William J. Spiegelberg.
Shriners Hospital for Crippled Children, Chicago \$1,000 by the will of the late Anton J. Cermak.
St. Luke's Hospital, New York more than \$1,000,000 from the estate of Miss Laura Shannon.
Central Dispensary and Emergency Hospital, Washington, D. C. \$50,000 from the estate of Simon Kann.
St. Margaret's Hospital, Kansas City \$10,000 from the estate of Langdon Bacon.
Fairview Hospital, Great Barrington, Mass. \$2,000 from estate of Charles S. Rackemann.
Children's Mercy Hospital, Kansas City \$25,000 from the estate of John M. Butler.
Memorah Hospital, Kansas City \$25,000 from the estate of Dr. John S. Lichtenberg.
Methodist Episcopal Hospital, Brooklyn \$20,000 from the estate of William L. Felter.
Olean General Hospital, Olean, N. Y. \$30,000 from the estate of Melvin C. Follett.
Emanuel Hospital, Portland, Ore. \$8,000 by the will of Carl A. Carlson.

Society News—Dr. Arno B. Luckhardt, Chicago, was elected president of the Federation of American Societies for Experimental Biology at its annual meeting April 12, and

Dr Frank C Mann, Rochester, Minn., secretary. These men hold the same office in the American Physiological Society. The next annual meeting of both organizations will be in New York.—W M Clark, Ph.D., Baltimore, was named president of the American Society of Biological Chemistry, April 10, and Henry A Mattill, Ph.D., Iowa City, secretary. New York was designated as the place for the next annual meeting.—The American Association of Anatomists will hold its next annual session in Philadelphia, March 28-30 1934. George E Coghill, Sc.D. Philadelphia, and George W Corner, Rochester, New York, are president and secretary, respectively.—Dr Carl V Weller, Ann Arbor, was installed as president of the American Society for Experimental Pathology at its annual meeting, April 12. Dr Simeon Burt Wolbach, Boston, was named president-elect, and Dr Charles Philip Miller, Jr., Chicago, reelected secretary. The next annual session will be in New York.—The annual meeting of the American Home Economics Association will be held in Milwaukee, June 26-30. Dr Morris Fishbein, Chicago, editor of *THE JOURNAL*, will address the association, June 28, on "Evaluation of Proprietary Foods."

CANADA

Personal—Dr William H Hill, Edmonton, has been appointed medical health officer of the city of Calgary and superintendent of the Calgary General Hospital to succeed Dr Duncan Gow.—Dr James B Collip, professor of biochemistry, McGill University Faculty of Medicine, Montreal, has recently been elected a Fellow of the Royal Society of London.—Dr Louis de L Harwood, dean of the University of Montreal Faculty of Medicine has been appointed superintendent of the Radium Institute of the Province of Quebec.—Dr Angus D McLachlin a 1932 graduate of the University of Western Ontario Faculty of Medicine, London, has been awarded a Rhodes scholarship to spend three years at Oxford University, England, where he will study physiology.

Annual Meeting of Canadian Medical Association—The sixty-fourth annual session of the Canadian Medical Association will be held in St John N B, June 19-23 under the presidency of Dr George A B Addy and with headquarters at the Admiral Beatty Hotel. The first two days will be devoted to meetings of the council and the scientific program will begin Wednesday, June 21. Among speakers listed on the program are

Sir Humphry Rolleston England British Pioneers in the Treatment of Tuberculosis
Prof Lyle Cummins Cardiff, Wales Blood Changes Noted in Tuberculosis.
Dr Alan G Brown, Toronto Importance of a Correct Diet in Childhood
Dr Frank H Lahey Boston Gout
Dr Herbert K. Detweiler Toronto The Role of Allergy in Disease

Dr Robert Muir, Glasgow, Scotland, will deliver the Lister Oration, which is open to the public, Wednesday evening

LATIN AMERICA

New Surgical Society—The Mexican Academy of Surgery was recently formed with the following officers: Drs Gonzalo Castañeda, president, Luis Rivero Borrell and Manuel Gea Gonzalez, vice president, and Manuel A Manzanilla, secretary

PUERTO RICO

Personal—Drs Ramon M Suarez, San Juan, and Manuel Guzman Rodriguez Mayaguez, have been appointed members of the Board of Medical Examiners of Puerto Rico succeeding Drs Alfredo Ortiz Romeu, San Juan, and Manuel A Astor, Arecibo

FOREIGN

Typhoid Epidemic—Four hundred persons have died in a typhoid epidemic in Siberian regions contiguous to the Manchurian border, according to the *Chicago Tribune*, April 26. The disease was said to be spreading toward Manchuria. Manchurian authorities have quarantined the frontier.

British Medical Association—The one hundred and first annual session of the British Medical Association will be held in Dublin, July 21-29. The annual representative meeting will begin Friday, July 21, and continue the next three week days. The annual general meeting will be held Tuesday afternoon, July 25 and the scientific sessions will occupy the next three days. Saturday, July 29 will be devoted to excursions to places of interest. Dr Thomas G Moorhead, regius professor of physic, Trinity College, Dublin, is the incoming president of the association.

University of Zurich Limits American Students—Entrance requirements for American students who wish to

enter the University of Zurich Faculty of Medicine, Zurich, Switzerland, have been made more strict, according to an announcement sent by the rector of the university to the United States Department of Education. Prospective students must now present a diploma of graduation from a recognized college or university transcript of college records only students who have received A or B ratings, or at least 80 points, being acceptable a certificate as to sufficient knowledge of German, and a declaration that the student has not been refused admission to a recognized American university.

Society News—The thirteenth International Neurologic Reunion was held in Paris, May 30-31, at the Salpêtrière. Subjects discussed included cerebral and spinal serous meningitis and exploration of the cerebral cavity by injections of air.—The Hungarian Ophthalmological Society has recently named the following American physicians honorary members: Drs Harvey Cushing, Boston, George E de Schweinitz, Philadelphia, Edward V L Brown and William H Wilder, Chicago and William H Wilmer, Baltimore.—The third International Congress for Experimental Cytology will be held in Cambridge, England, August 21-26. The following subjects will be discussed: cell respiration and metabolism, cell form and function as demonstrated by recent advances in tissue culture, electrophysiology of the cell, mechanics of development, and cultivation of animal and plant viruses.

International Hospital Congress in Belgium—The third International Hospital Congress will be held in Knocke-sur-Mer, Belgium, June 28 to July 3. Reports of ten international study committees will form the basis for discussions. Their subjects include construction, equipment and technic, administration and housekeeping, finance and bookkeeping, legislation, care of the patient in the hospital, patients' food, personnel, statistics and outside connections with the hospital. Any resolutions adopted will be passed on to the League of Nations and the governments concerned. Following the congress, a five days study tour of Holland has been arranged by the Dutch Hospital Association to visit hospitals and places of interest, July 4-9. Detailed programs may be obtained from Messrs W Kohlhammer, Verlag, Urbanstrasse 12/16 Stuttgart, Germany. Communications concerning the congress should be addressed to Dr W Alter, Ernst Ludwig Allee 2, Buchschlag, Hessen, Germany.

Status of Jewish Physicians in Germany—The following items are taken from recent issues of German weekly publications. Twenty professors at Oxford and Cambridge wrote to the *London Times* protesting against the dismissal of Bernhard Zondek because of his being Jewish. They emphasized the fact that they acted on scientific principles only because through Zondek German science had risen to fame.

Because of the law regarding officials and other laws, the Prussian Minister of Culture gave leaves of absence to Dr Hermann Freund, professor of pharmacology at Münster; Dr Carl Prausnitz, professor of hygiene, and Dr Hans Winterstein, professor of physiology at Breslau; Dr Theodor Meyer-Steinig, associate professor of the history of medicine, and Dr Hans Simmel, associate professor of internal medicine at Jena.

It is reported that Geh-Rat Prof Dr Ferdinand Blumenthal the accomplished director of the Cancer Institute at the University of Berlin, has asked to be released from his office.

On the basis of the law regarding officials, the following were granted leave of absence from the University of Berlin: Dr Karl Birnbaum, professor of psychiatry; Dr Franz Blumenthal, professor of dermatology; Dr Hans Friedenthal, professor of physiology; Dr Friedrich Franz Friedman, professor of tuberculosis research; Dr Peter Rona, professor of physiology and Dr Konrad Cohn docent in dentistry. Dr A Wolff-Eisner, professor of internal medicine, was dismissed from teaching. Geh-Rat Dr Moritz Borchardt, former director of the surgical department of the Moabit Hospital was replaced by Prof Dr Wilhelm Baetzner. Prof Dr Schück, director of the city hospital in the urban district, was given a leave of absence.

Dr Wilhelm Peters professor of psychology at Jena was dismissed and was replaced by Prof Dr Annelies Argelander. Dr Emil Klein professor of dietetics and natural therapy at Jena, was dismissed and was replaced by Prof Julius Gröber.

Dr S Rosenbaum, chief physician of the University Pediatrics clinic in Leipzig, was granted a leave of absence.

Deaths in Other Countries

Joseph Priestley Smith, emeritus professor of ophthalmology University of Birmingham, England, died, April 30, aged 87.

Thomas and Jones

The obituaries of Sir Robert Jones did not give due credit to his great inheritance from his uncle and master, Hugh Owen Thomas, or indicate how his work though full of originality and beyond all praise, was but a development of that of the latter. In the history of surgery, Thomas stands out as a heroic figure. A general practitioner among the poor of Liverpool dockland, without the advantage of any hospital appointment, he revolutionized the treatment of tuberculous joints. For a time he was ignored by the surgical authorities of his day, but this meant nothing to him. Devoid of vanity or ambition and devoted to his work, he was concerned only in developing his methods and benefiting his patients. But he did not hide his scorn of surgeons. With his usual penetrating criticism Lord Moynihan says of him "He knew little of pathology and appeared to have been either ignorant of, or at least uninterested in the appearance of diseased or deformed parts as seen during operation or after death. But of the changed appearances and function of morbid bones or joints, of the means other than operation to be used to aid nature in its efforts at restoration, no man ever knew so much. To the principle of rest he gave a meaning extending far beyond that of Hilton."

As a means of ensuring prolonged rest, for the treatment of tuberculous joints, he invented the most perfect splint ever known. His knee splint is designed to prevent movement of the knee and yet leave the joint uncompressed and the circulation unhindered. In the war its use for the treatment of fractures of the femur had to be taught again by Jones and Major Maurice Sinclair. Jones described Sinclair's Fracture Hospital as "the last word in military surgery." In his book on 'Fractures,' a product of the war, Sinclair refers to Thomas's splints as 'the greatest advance in the treatment of fractures in modern times' and as 'instruments so perfect that all modifications do but reduce their efficacy.' They have indeed rendered the name of Thomas immortal. However, it is generally forgotten that they were not merely the work of a clever mechanic but the means of putting into practice the principles of one of the most original and independent minds. Thomas was the first to insist on the need of keeping the paralyzed muscles relaxed in poliomyelitis. In 1876 he described under the name of 'damming' what English and American surgeons call Bier's treatment though this dates from 1903. He was among the first to use percussion for ununited fractures. He anticipated, as Keith points out, Wolf's law of the influence of strain on bone. His work was entirely original, he derived nothing from predecessors in orthopedic surgery. His grasp of principles and his skill in applying them were extraordinary. In his appreciation of the fundamental principle that nature is always the healer he is compared by Keith to Hunter.

As a boy, Jones spent his holidays among the lathes and carpenter's benches where Thomas was working, and from the age of 16 when he became a medical student, helped him in his practice. The association continued until 1891, when Thomas died and Jones was 33. In his further career Jones so to speak, stood on the shoulders of Thomas. He had the same extraordinary grasp of principles as Thomas but also the opportunity for extending them to the field of operative surgery. The two form a combination unique in the history of surgery and their achievements must be regarded as forming a single whole, the uncle's life being prolonged, as it were in the nephew's. Jones has been called "the greatest orthopedic sur-

geon of all time," but, paraphrasing Swinburne's comparison of "George Eliot" and Charlotte Brontë, it may be said "Jones was the greater surgeon but Thomas the greater genius."

Treatment of Chronic Typhoid Carriers

The Medical Research Council has published a report by Prof. C. H. Browning and others on research done in the pathologic department of Glasgow University on chronic typhoid carriers. A considerable proportion of typhoid convalescents are temporary carriers. Carriers are divided into fecal and urinary, according to the habitat of the persisting organisms. In the majority of fecal carriers the bacilli live in the gall-bladder, which is usually more or less inflamed. Urinary carriers excrete the bacilli intermittently. Though usually there is no pyuria, the bacteriuria is probably due to focal infection of the kidney and rupture into the renal tubules of minute abscesses. When the bacilli persist in the urine something pathologic in the urinary tract, such as malformation or calculus, is the rule. Typhoid and paratyphoid bacilli may persist also in subcutaneous abscesses, periostitis and osteomyelitis. Nonsurgical treatment with intestinal antiseptics, vaccines and bacteriophages and by dietetic methods, to alter the reaction and flora of the intestine, have all been unsuccessful. On the other hand, when the gallbladder was the site of infection, operation on that organ has given good results. Three chronic carriers were thus cured at the Western Infirmary, Glasgow.

The German Persecution of Jewish Physicians

The British Medical Association has received letters from Jewish physicians in Germany inquiring as to the prospects of medical practice in Great Britain. In an editorial, the *British Medical Journal* expresses sympathy but points out that there is no medical reciprocity between Germany and Great Britain. Qualifications in one country give little or no privilege in another. Hence German diplomas are not registrable here. In replying to correspondents, the medical secretary of the association states that two conditions must be fulfilled by colleagues who can no longer practice freely in Germany. First, they must obtain a British qualification, with all that that entails, second, they must comply with the requirements of the aliens act. In the ordinary way, permission is readily given to reputable foreigners who wish to pursue medical studies here. But the official procedure might change if many applications came from one country, and the attitude of the medical schools and examining bodies would also have to be reckoned with. The English friends of these unfortunate physicians whose eyes were now turning toward England would do well to ascertain the views of the government before holding out encouragement to them.

British Spas

For years, it has been a custom for wealthy invalids to resort to spas on the European continent which offered attractions of various kinds not found at home. But in this period of unprecedented financial depression a movement arose to endeavor to keep our invalids at home, and the British Health Resorts Association was formed to improve our spas. At a meeting of the association at Leamington Spa, Lieutenant Colonel Byam, lecturer on tropical hygiene at St. George's Hospital, suggested that for the tropical invalid every spa should not claim to cater that some specialization was necessary. Dr. P. H. Manson-Bahr, physician to the Hospital for Tropical Diseases, urged that every case of tropical disease be investigated before spa treatment was begun. The ordinary spa treatment was quite unsuitable for the acute stages of sprue, amebic dysentery, malaria and the main tropical diseases. The necessity for a physician experienced in the subject was paramount. Lord Horder opened a discussion on the treatment of circulatory diseases at spas. He considered that at present spa facilities in England were scanty. The spas of this country

were quite capable of giving the requisite treatment, but specialization was essential. In heart cases, complete rest physical and emotional was paramount. Thus the foreign spas could guarantee. It was an anomaly that British medicine, which had led the world in the last twenty-five years in regard to cardiovascular diseases, should allow its patients to go to Nauheim and other foreign spas. Dr J Strickland Goodall (cardiologist) said that there was no reason why British spas should not be able to give all the treatment available on the continent. He suggested that special provision should be made at the spas for orthodox Jews who had until lately gone to Nauheim.

Treatment of Arthritis Deformans

Before the Société de chirurgie, Mr Simon of Strasbourg described recently an original method of treatment for arthritis deformans with which he has secured excellent results. While observing in Strasbourg results that Leriche secured in these cases by performing parathyroidectomy, he noticed that, in some cases in which the surgeon had not found the parathyroid glands, the operation was nevertheless successful. From this fact he concluded that mere surface irritation of the thyroid, during prolonged operative maneuvers, played a part in these ameliorations. Furthermore, he assumes that thyroid insufficiency is often a cause of arthritis deformans. This conclusion was the point of departure for the method that he devised. He exposed the thyroid with a simple incision and painted the surface with a phenol solution. In ten cases with one exception, he secured an immediate considerable amelioration of the rheumatism. The patients recovered the normal amplitude of movements and the pain subsided. With regard to the movements the amelioration was only transitory, but the pain, although it returned, was much more easily borne than before.

Conjugal Tuberculosis

The Assemblée générale de la médecine française, which meets in Paris two or three times a year and is made up of physicians who come from all departments of France, shows indications of becoming one of the most important learned societies of France. The amount of documentary evidence that is presented has much greater value than the isolated observations collected by the heads of hospital departments. The observations presented are made among various groups of clients in a family environment, the elements of which are well known to the practitioner through contacts extending over several years. The topic studied by the last assembly was 'Conjugal Tuberculosis.' Conjugal tuberculosis—that is the infection of one spouse by the other—is undeniable. Such infection is not, however, inevitable and is observed in only 10 per cent of the couples of which one spouse is tuberculous. One often discovers after the death of the affected spouse signs of latent tuberculosis in the survivor. The spouse who is tuberculous is nearly always found to have tuberculous antecedents. Resistance to contagion increases with age, and, in the cities especially, the subject tends to acquire a degree of immunity. Young women brought up in mountain regions who come to the cities and marry, furnish a large proportion of the cases of conjugal tuberculosis. Such cases are more rare in some regions—for example, the Provence and the Bearn where tuberculosis is not as common as elsewhere. There are a great many more widowers than widows as a result of the death of a tuberculous spouse, in the center of France. In Brittany the reverse is true, possibly because of the greater frequency of alcoholism among the male population. In general, women are more frequently affected with tuberculosis during conjugal life. Early tuberculosis following marriage is often

observed and usually develops rapidly. Pregnancy is generally regarded as an aggravating factor. Likewise, the serious menace of contamination for young children brought up in a home in which one of the parents is tuberculous, unless such children were inoculated with the BCG vaccine soon after birth, was emphasized. Contamination among married couples is the exception whereas contamination of the child is the rule. The assembly, before adjourning, adopted unanimously the following resolution:

Recognizing that the contamination of the adult is rare but does exist the institution of prophylactic measures is in order but the protection of young children should be intensified in view of the extreme danger of contamination.

The following topics were selected for the next meetings: "The Future of Pleuritics," "The Frequency and the Present Physiognomy of Syphilis," "Convulsions in Children and Their Remote Prognosis," and "Goiter in France."

Prophylaxis of Deafmutism

Dr A Malherbe, chief physician of the Institut national des sourds-muets in Paris, surveys in the *Bulletin médical* the results of his long experiments. In his opinion, the deafmute is only the deaf person who has lost his hearing when under 7 or 8 years of age. He does not speak because of his inability to recognize spoken words, as he does not hear them but the cerebral speech center he still possesses intact. If the lesion of the ear causing his deafness develops around age 7, although he has learned to speak he soon loses the use of spoken language. If the lesion intervenes after age 7 or 8, he may no longer hear but may continue to speak, making use of such words as he has learned. Congenital deafness constitutes scarcely a third of the cases and affects chiefly males. Among the causes of nervous atrophy, he cites malformations of the auditory apparatus, in which the role of hereditary alcoholism, and congenital tuberculosis and/or syphilis is unquestionable. The effects of consanguinity have been greatly exaggerated. Only morbid consanguinity can be incriminated. Among the causes of early acquired deafness, leading almost certainly to deafmutism, the author mentions cerebrospinal meningitis, convulsions, scarlet fever, measles, numerous infections of the rhinopharynx involving the ear, and traumatism. Malherbe calls attention to a neglected cause of deafness arising during the first days after birth. At birth the tympanic cavity is filled with a mass of mucus, which is resorbed only gradually and constitutes an excellent area for the development of microorganisms coming from the rhinopharynx. This infection goes on quietly, for the tympanum is never perforated. Nevertheless, it brings about the denudation of the ossicles and grave and permanent changes of the labyrinth leading to deafness. The author considers disinfection of the rhinopharynx at birth the best preventive measure against deafmutism just as disinfection of the conjunctivae is resorted to, to prevent ophthalmia in the new-born.

The Old Headquarters of the Academy of Medicine

The old headquarters of the Academy of Medicine, in the rue des Saints-Peres, which were abandoned thirty years ago for the new magnificent quarters that it now occupies in the rue Bonaparte, have been undergoing some much needed repairs. The discoveries that have been made in the old quarters occupied by the academy for ninety years awaken surprise. The small hall in which the council met had a low ceiling and presented a paradoxical state of uncleanness. When the academy moved to its new quarters, the old dusty carpet that covered the floor of this sanctuary was taken up. Under this carpet was found another carpet also worn and even more dusty than the top carpet. Under the second carpet was found a third, and, the excavations being continued ten old carpets none of which appeared to have been ever subjected to a cleaning process, during the time that successive generations of venerable

savants—from Depuytren to Pasteur and Dr. Roux—had passed over them, were removed! What a haunt for streptococci, staphylococci and tubercle bacilli the Academy of Medicine had become! And from these environs were promulgated by the great apostles of hygiene the far-reaching precepts of antiseptics. However, they all died at an advanced age, without their health having been impaired in the slightest by this uncleanness. But they spent only a few hours each week in this environment.

Research on Roentgen Rays and Light

The Deutsche Röntgengesellschaft and the Deutsche Gesellschaft für Lichtforschung held recently a joint session in Bremen. The Rieder gold medal was awarded to Prof. Alban Köhler of Wiesbaden, who has become widely known through his work on "Die Grenzen des Normalen und die Anfänge des Pathologischen im Röntgenbild." Considerable time was devoted to papers and discussions on the roentgenologic diagnosis of the cranium and of the central nervous system, particularly with respect to their value for neurology, internal medicine and surgery. In this field Peiper of Frankfurt-on-Main presented a paper on "The Contrast Method in Neurology," Löhr and Jakob of Magdeburg on "Arteriography of the Blood Vessels of the Brain," Wustmann of Düsseldorf on "The Contrast Method as Applied to the Central Nervous System," and des Plantes of Utrecht on "The Roentgenologic Examination of the Cranium." A number of the papers were devoted to the roentgenologic diagnosis in obstetrics. The prognosis of the course of a birth has become more certain through roentgenologic diagnosis. Interesting details on these questions were furnished particularly by Gauss of Würzburg, Schulze of Berlin and Schaefer of Göttingen. Special attention may be directed to the paper of Boedeker of Bremen on roentgenologic serial examinations for the diagnosis and treatment of pulmonary tuberculosis. Particular interest attaches to the paper of Holthusen of Hamburg on ray therapy as applied to malignant tumors. He demands unconditionally roentgenologic penetrating treatment postoperatively in order to kill the scattered cancer cells. In cases in which operative treatment is not possible, primary penetrating roentgen treatment in combination with radium is exceedingly important. Engelmann of Hamburg reported the results of three years' experience with radium in the treatment of the upper respiratory passages. Rajewski of Frankfurt-on-Main brought out that tissue cultures, particularly in the hanging drop, offer good opportunities for the study of the effects of various kinds of rays on the cells. Glocker of Stuttgart discussed the "Physical Bases of the Biologic Effects of Rays" and emphasized the importance of the constitution of the individual with reference to reactions to roentgen rays.

The session of the Deutsche Gesellschaft für Lichtforschung brought out a thorough discussion of ray treatment in tuberculosis. The topic was introduced by Bernhardt of Saint Moritz, the founder of light therapy in mountain regions, while Stühmer of Münster spoke on the organization of lupus treatment. Lomholt of Copenhagen reported on light therapy of lupus, after the method of the Finsen Institute, by the application of concentrated carbon arc light, in which the infra-red heat rays, which damage the skin, are filtered out, while the ultraviolet heat rays are directed to the diseased area of the skin through a quartz lens that allows them to pass. That in low regions the application of natural available light rays will accomplish similar results to those reported for mountain regions was stressed by Schulze of Giessen. Holfelder of Frankfurt-on-Main spoke on the differentiation of roentgenologic and surgical treatment in tuberculosis of the bone.

The Adaptability of the Nervous System

Prof. A. Bethe, an authority in physiology at the University of Frankfurt-on-Main, spoke recently before the Berlin Verein für Innere Medizin on the topic "Adaptability of the Nervous System." By plasticity Bethe understands the quality of adaptation to momentarily prevailing conditions. The organism is constantly subjected to new conditions. After experimental exchange of the points of insertion of antagonistic muscles, and after crosswise healing of nerves of different functions—the normal motions, reflexes and sensations are gradually restored, although the central connections are now entirely different from what they were naturally. From this observation it is evident that the normal central innervation areas do not possess a specificity. Other experiments show that the previous assumption of the existence of preformed coordination centers can scarcely be upheld. Further proof is found in the fact that the coordination of the movements of locomotion, which is so firmly established and which appears so specific in all animals, is changed at once and in the most diverse ways if one or more extremities are removed. A dog without front legs adopts a locomotion similar to that of the kangaroo, while a dog without hind legs walks on his front legs. These happenings in the nervous system cannot be understood on the basis of the previous assumption, namely, of reflexes controlling isolated areas existing side by side. A more plausible assumption is that the whole nervous system, with the entire innervated periphery, constitutes one unit, and that every stimulation extends more or less throughout the nervous system. In spite of the large amount of material available, only the first steps in reorganizing our conceptions of the mechanism of central happenings have been taken as yet. That a revision of our views of the *modus operandi* of the nervous system is necessary can hardly be denied in the face of the many recent observations.

During the general discussion, Professor Goldstein, a neurologist and formerly an ordinarius at the University of Frankfurt, said that also in human pathology the endeavor to restore the unity of the organism is demonstrable. In hemianopia, loss of vision affects only the perimeter of the visual field, which remains almost complete. This modification can be shown by the fact that through a slight turning of the eye no longer the macula but another portion of the retina becomes the place of keenest vision. Professor Kramer, chief physician of the Berlin Neurologische Universitätsklinik, pointed out that there is an important exception in the exchange of nervous functions. The facial nerve cannot be replaced by the accessorius. Movements of the muscles originally controlled by the accessorius continue to occur along with the other movements, and the motions of mimicry are not restored to their original form. Possibly this exceptional status of the facial nerve can be explained by its relation to the external world.

ITALY

(From Our Regular Correspondent)

March 15, 1933

Congress on Rheumatism

At the third International Congress on Rheumatism, Professor Sante Pisani of Florence spoke on chronic rheumatism, designating two types of manifestations: chronic polyarticular rheumatism secondary to acute polyarticular rheumatism, and primary chronic polyarticular rheumatism. The former is a prolonged form of the acute type, the establishment of chronicity is heralded by the persistence of the changes in the general condition and by pains in the joints. Primary chronic rheumatism differs from the preceding type in that it is never associated with cardiac localizations. It is preceded by premonitory symptoms (changes in the general condition) and is sometimes manifested at the start by severe but transitory

inflammatory attacks, which produce articular deformations after a long period

Professor Frugoni of Rome brought out that in the genesis of tuberculous rheumatism, as in other infectious forms of rheumatism, there intervenes a factor of nonspecific hypersensitiveness of the tissues, as recently demonstrated by Chini and Magrassi. The peculiar affinity of each virus is responsible, to a certain extent, for the localization and the evolution of the lesions

A New Medicosurgical Society

The Società medico chirurgica Veneziana recently founded, held a meeting under the chairmanship of Prof G B Fiocco, at which papers on many subjects were presented

Magni spoke on the results of some 2,000 vaccinations against diphtheria, with reference to vaccination with a single dose of anatoxin. Applying the original technic of Ramon, with three successive doses of anatoxin the speaker obtained in 256 children, who out of 1,174 had presented a positive Schick reaction, a negative reaction, sixty days later, in 90.5 per cent of the cases so treated. To 195 Schick-positive children (out of 256) the speaker applied Termi's anatoxin, injecting 1.5 cc. (45 units) at one time and secured, after forty-five days, a Schick-negative test in 87 per cent of the cases

Lolli spoke on the Löwenstein method in tuberculous bacillemia. This method reveals the presence of bacillemia in 80 per cent of the cases of tuberculosis, in tuberculous rheumatism, and also in multiple sclerosis which is contrary to the beliefs held by many Italian and foreign authors. The speaker carried out research in eight cases of tuberculous meningitis, three cases of acute miliary tuberculosis, three cases of rheumatism, and one case of active tuberculosis of the bone. He used the various culture mediums of Löwenstein, comparing them with the culture medium of Petragani. He obtained no blood culture positive for tubercle bacilli, and he found the culture medium of Löwenstein inferior to that of Petragani for the cultivation of the bacilli of tuberculosis

Polichetti presented his observations in a rare case of Dupuy's disease, in a patient aged 37, who had suffered a torsion of the right shoulder resulting from a sudden movement. Six years later, he developed lymphangitis of the arm and adenitis of the right axilla with pain in the shoulder and restriction of movement. A roentgenogram revealed an irregular shadow above the head of the humerus, the objective examination showed hypotrophy of the muscles, particularly of the deltoid, but without tumefaction or fever. The calcified focus having been removed surgically, a recovery was effected in thirty-five days

Mozzetti and De Marchi experimented with the action of the follicular fluid in guinea-pigs and rabbits subjected to subtotal ovariectomy and were able to note a frank positive reaction of the cervical stump. They demonstrated in this manner that the hormone action of the follicular fluid affects not only the uterus as a whole but also certain segments (for example the cervix). The speakers saw in the experimental results secured an explanation of certain revivifying manifestations noted in the stump of persons subjected to subtotal hysterectomy, concomitant with the menstrual cycle

Leuti spoke on so called pleural stones describing a rare case of calcareous deposits, which presented a bilateral symmetrical localization in the diaphragm

The Welfare of Mothers and Children

A recently published report gives a survey of the activities of the Opera nazionale per la maternità e la infanzia during the seven years of its existence (1926-1932). By means of fifty ambulant chairs of puericulture, 500 obstetric and pediatric consultants, and the supervision of several thousand institutes (more than 4,000 of which were aided directly), the society has aided more than one million mothers and three million

children. In 1932 alone, 70,956 abandoned and needy gravidæ, 174,317 abandoned and needy mothers with children under 3 years of age, and 352,606 children, among which there were 47,426 illegitimate children recognized by their mothers, were aided. In 1926, the total number of infant deaths in Italy exceeded 48,000. In 1932, after a slow but constant downward trend, the figure reached 37,000. In 1925, the total number of deaths of children up to 4 years of age was 217,000, in 1930 it dropped to 176,000 and has presumably diminished further during the past two years, although the statistics for this period have not yet been published. The total number of deaths, in 1925, of gravidæ, resulting from childbirth, was 3,111, while in 1930 the figure dropped to 2,900

Meeting of Laryngologic Society

The Società di laringologia held its twenty-eighth national congress at Rome, under the chairmanship of Professor Bilancioni, director of the University Clinic. The congress was attended by many foreign specialists. The chief topic, "Reflex Neuroses of Nasal Origin," was presented by Professors Carrari, Giussani and Palestini, who described the disturbances that are produced in remote organs, due to actions resulting from excitation of the nasal mucosa. Such reflex disturbances find in the trigeminal and in the neurovegetative system their distributive mechanism. The following topics were then discussed: "Adenoid Prophylaxis in Children," "The Organization of the Otorhinolaryngologic Service in Hospitals" and "University Instruction in Specialties." With reference to the last topic, it was admitted with regret that the number of chairs had been reduced in recent years. The next congress will be held at Bolzano

CAPE TOWN

(From Our Regular Correspondent)

March 31, 1933

The Annual Medical Congress

The Medical Association of South Africa will hold its annual scientific meeting, popularly known as the medical congress, at Cape Town in September. The president of the congress is Dr E B Fuller, a consulting urologist and one of the pioneers in his specialty in South Africa. The sessions will be held in the recently completed buildings of the Cape Town University at Groot Schuur, which were planned by Mr Solomon, an architect of distinction, who died recently. They are among the most beautiful in the country and are set in a picturesque environment. The program of the congress provides for three plenary sessions, which will be devoted to discussion on maternal mortality, diet in tropical climates, and medicolegal problems in general practice.

An attempt is being made to establish a special subsection at the congress for the discussion of comparative medicine. At Onderstepoort, the veterinary laboratory and research station near Pretoria, a well trained staff has been working for many years on animal diseases. Sir Arnold Theiler initiated these investigations into avitaminosis, veterinary bacteriology and the pathology of malignant disease in animals, and excellent work has been done. De Koch, a pupil of Aschoff, has published original work on the results of splenectomy in sheep and horses. Jackson and de Kock have studied the curious pulmonary adenomatosis in sheep, while Green and others have written on the various deficiency diseases and stock poisons. The Onderstepoort institution now is studying the diseases of wild game in the Kruger reserve. The result of all these researches are almost unknown to the medical profession, although they may have an intimate bearing on human disease. It is suggested that there should be a definite collaboration between medical men and veterinarians for the purpose of discussing pathologic questions that are of mutual interest. The incidence of tuberculosis is one of these questions in which such cooperation may be of great help in this country.

The Sale of Poisons

Recently both chemists and medical men have agitated for some modification of the law which now permits the sale of poisons by grocers and shopkeepers, provided such poisons are classed as domestic or agricultural necessities. In the medical, dental and pharmacy act, section 50 prescribes that scheduled poisons shall be sold only by chemists, but the succeeding section provides that poisonous substances for domestic and agricultural use may be sold in the shops of general dealers without the useful restrictions that are imposed on the chemists. The main difficulty in obtaining a modification of the act is the opposition of the chambers of commerce, which object to any restriction on the sale of articles that have been allowed to be vendd by bazaars and shops. Among these articles, proprietary medicines, generically known as 'Dutch household remedies' occupy an intrenched position. They are sold in great quantities, and while their therapeutic usefulness is almost nil, their alcoholic content is in some cases remarkably high. Such things as compound solution of cresol and sodium hydroxide are freely sold, and it is well known that both substances are frequent causes of poisoning. Chemists and physicians have now combined to urge that some restriction be placed on the free sale of such substances but it is unlikely that their representations will have much effect with a government that legislates mainly in the interest of the farming community.

Disciplinary Cases

The South African Medical Council, at its session this month, had before it two interesting disciplinary cases. In one a senior practitioner was found guilty of signing a death certificate without having satisfied himself that the facts were fully and correctly stated. Laxity in certification is unfortunately common and the council has already issued warning notices about it. In this case it found the practitioner guilty of improper conduct and reprimanded him. In the second case another senior practitioner in country practice, was charged with having improperly made certain statements about a patient to the police and of having examined the patient without his consent. The case created a great deal of local interest, for the parties involved were fellow practitioners in a small country town. From the evidence, it appeared that the accused had acted in his official capacity as district surgeon. The council found as a result, that he was not guilty of improper and disgraceful conduct and that he had acted under statutory authority in examining the patient, and dismissed all the charges against him.

The New Cape Town Hospital

After nearly six years of weary waiting the magnificent new hospital which is also to be the teaching hospital of the university is under construction. The site is on the northern mountain slope, on ground belonging to the Rhodes estate. It needed leveling and a considerable amount of money has been spent on this necessary preliminary. The superstructure is to be erected at a cost of £500,000. The hospital is to be a large block, with the departments arranged in the several stories and with ample outpatient provision. There is to be a fee paying ward and various special departments. The design of the hospital has been criticized in some quarters, but the architect, Mr Cleland of the public works department, is an authority on hospital planning and his design has been planned in close collaboration with the medical and administrative staffs. As a matter of fact, the hospital when completed will be one of the best in Africa. Considering the difficulties that had to be overcome—not the least of which is the separation of white from Negro patients and the problem of ward orientation—Mr Cleland's plan will be generally approved of by those who are capable of judging. Cape Town has long wanted a modern hospital. The institution that at present serves as such dates

back to the early sixties of the last century and is in all respects unsuitable. The new hospital will accommodate 400 patients and will be served by three adjacent district hospitals, of the cottage hospital type, which are comparatively modern buildings.

Physical Therapy in the Netherlands

At the suggestion of J van Breemen, director of the Institute of Physical Therapy in Amsterdam, an investigation was made into the status of physical therapy in the Netherlands. The inquiry covered the year 1929 and a part of 1930. According to van Breemen, the essential task of physical therapy is to study the application of physical stimulus to healthy and ill persons. Among the methods that may be employed are climato therapy, inhalation therapy, balneotherapy, thalassotherapy, hydrotherapy, thermotherapy, massage, gymnastics, mechanical orthopedics, electrotherapy and heliotherapy. The results of the inquiry are summed up in the following conclusions: 1 Physical therapy is employed in the Netherlands in all its forms, not only in a number of specialized institutions but also in the hospitals and in private practice. The organization of physical therapy is not yet complete. 2 Management, surveillance and medical control of physical therapy are lacking in some instances. 3 The diplomas and titles connected with the use of physical therapy should be regulated and protected by law likewise certain conditions should be met. 4 A special preparation of physicians will make possible a genuine medical surveillance of physical therapy.

Restrictions on the Number of Medical Students

Prof W Storm Van Leeuwen defends in the daily press the creation of restrictions on the enrolment of students in universities and particularly in the faculties of medicine. He sees no harm in special entrance examinations, but he would like to see established for each university the maximum number of students that may be enrolled in each faculty. That would constitute the first restriction. A second restriction may be established by subjecting medical students to special entrance tests. Those who succeed in passing such tests would be placed on a list in accordance with the total number of points secured. From those with the lower grades could be eliminated whatever number would be necessary to reduce the number of entrants to the basis required.

Bacillary Dysentery in Amsterdam

In the *Nederlandsch Tydschrift voor Geneeskunde* Dr Charlotte Ruys publishes the results of her laboratory research on an epidemic of bacillary dysentery that occurred recently in Amsterdam. She concludes that bacillary dysentery of the Sonne type is endemic in Amsterdam. In the winter of 1931-1932 there was also a slight outbreak of the Flexner type. After recovery, patients may eliminate for a long time dysentery bacilli in the feces. Contacts have doubtless great importance from the point of view of contagion.

Social Hygiene in the Netherlands

Dr Eykel, inspector general of public health, has published a book entitled 'The Work of Social Hygiene in the Netherlands' in which he writes first of the various organizations that control the public health services in the Netherlands. The remainder of the book is devoted to child hygiene and the crusades against tuberculosis and venereal diseases. Dr Eykel does not consider in his book the social measures adopted against diphtheria, trachoma, blindness and nervous diseases. These activities have not the same importance as the crusade against tuberculosis and syphilis.

Aid for Lepers

The Association for the Aid of Lepers, founded at Bandung, publishes a journal entitled *Pro Leprosos*. The purpose of the association is (1) to take an interest in the welfare of lepers, (2) to propagate ideas concerning the treatment of leprosy, and (3) to aid financially the application of curative methods. The editor of the journal is Dr. C. J. Wijckerheld Bisdom of Bandung, who is also the director of the association. Aid is given to lepers irrespective of race or religious faith.

Commemoration of the Third Centenary of Leeuwenhoeck

Ceremonies were held recently at Delft commemorating the three hundredth anniversary of the birth of Anthony Leeuwenhoeck. Many notables of the Netherlands attended. Professor Gutterink, rector of the senate. Prof. D. Arcy Wentworth Thompson, delegate from the Royal Society. Prof. J. Van Der Hoeve, president of the Leeuwenhoeck national committee. Addresses were delivered and a wreath was laid on the grave of the scientist in the old church at Delft.

BELGIUM

(From Our Regular Correspondent)

April 20 1933

Requirements for Specialists

After many long discussions, to which attention has been called in previous letters, the Royal Academy of Medicine of Belgium has concluded its preliminary studies and a bill has been introduced concerning the requirements to be met by specialists.

1 As supplementary to the medical studies properly so called and under the form of postgraduate instruction, tests are legally established covering a thorough preparation in the practice of internal medicine, general surgery and the various medical and surgical specialties.

2 Certification of specialists may be based on subjects compulsory instruction in which is provided for by article 14 of the law pertaining to higher instruction such for example, as internal medicine, general surgery, obstetrics and gynecology, pediatrics, ophthalmology, otorhinolaryngology, dermatology and syphilography, psychiatry, urology, legal medicine, bacteriology and radiology.

3 Instruction in the foregoing specialties is obtained in practice courses taken in a department of a university (or of a private hospital, on condition that such department be approved by one of the faculties of medicine of Belgium). Every candidate must, however, be enrolled in a Belgian faculty of medicine.

4 Such a course will comprise four consecutive years of residence and work in the fields of general surgery and internal medicine if full time is devoted to such study, or six years of part time work, at least two years of study for each of the medical or surgical specialties if full time, four years if part time.

5 Candidates who desire to practice in two specialties must take the courses prescribed for these two specialties. However, candidates who have fulfilled the requirements for general surgery may practice in gynecology and in urology, either separately or conjointly, provided they have passed the tests imposed for these two specialties.

6 A course may be taken partly at one institution of Belgium and partly in another and, with the consent of the faculty of medicine in which the candidate is enrolled, part of the course may be taken at a foreign institution.

7 Candidates in specialties of a medical or surgical nature are authorized to take part of their course in a general medical service or in a general surgical service, respectively.

8 The course pursued by a candidate is attested by a written statement signed by the department heads under whom the course was taken. This declaration must be officially recorded.

9 On completion of the course, the candidate must present himself before an examining board composed of five members, three of whom are particularly competent in the specialty concerned: the faculty professor, a professor of another faculty of medicine or the accepted department head, the head of the department in which the course was taken and two other professors of the faculty. The examining board is selected by the faculty of medicine.

10 The candidate must submit to the following tests: (a) thorough examination of a patient, (b) technical test, operation performed before the board, (c) presentation and oral discussion of manuscript or printed article or discussion of a topic previously announced by the board.

11 Two successive failures will eliminate a candidate definitively.

12 During a transition period covering the first six years following the promulgation of the present ruling, bearers of a legal diploma of doctor of medicine, surgery and obstetrics may, without taking the prescribed course, be admitted to the practical test for specialists after twelve years of experience in general surgery and internal medicine or after six years of experience in the other specialties.

13 To the candidate who has successfully passed the practical test under the aforementioned conditions there will be delivered an official certificate constituting the special diploma in the specialty or specialties concerned. This special diploma must be presented to the chairman of the medical commission of the district in which the graduate resides. The diploma is subject to legal confirmation.

Taking account of these various principles, the commission adopted the following regulations:

1 Public authorities shall prohibit the use of the title of specialist by any physician who has not passed the foregoing tests, subject to penalties similar to those imposed on persons who practice the art of healing without authorization.

2 In accordance with legal provisions to be adopted by the public authorities, positions as department heads in hospitals, institutes, polyclinics and dispensaries may be held only by bearers of a special diploma in the branches corresponding to the respective departments. Likewise, only holders of a special diploma may be approved by official organizations, societies or benevolent orders for the practice of internal medicine, general surgery, obstetrics and gynecology, pediatrics and the various specialties mentioned.

Automobile Accidents

The official statistics for Belgium show, in round numbers, 12,000 automobile accidents in 1927, 17,600 in 1929, 18,800 in 1930 and 18,700 in 1931. With relation to the number of cars in use and adopting 100 as the norm for 1927, the proportion of accidents in 1928 was 127, in 1929, 146, and in 1930 and 1931, 157. The number of persons involved increased one third between 1927 and 1931. For each 100 accidents in 1929 there were forty-eight persons injured, two of whom died, in 1930, forty-nine persons injured, with two fatalities, and, in 1931, forty-five injured, two of whom died. The preliminary report for 1932 shows an increase. In spite of these alarming facts, no legislation has as yet been enacted providing for the medical examination of drivers.

Prof. Albert Lemaire (1875-1933)

The unexpected death of Professor Lemaire, in the midst of full physical vigor and intellectual activity, caused consternation among the medical profession of Belgium. Albert Lemaire was widely known as a great teacher. As professor of clinical medicine at the University of Louvain he obtained recognition through his research on icterus and the anemias.

Deaths

Albert R. Mitchell & Lincoln, Neb., for seventeen years continuing a member of the Board of Trustees of the American Medical Association and chairman of the Board since June, 1922, died at his home in Lincoln of pneumonia, Mar. 29, aged 77 years. Dr. Mitchell was born in Cambridge, Ill., April 5, 1856. He received his M.D. degree from Rush Medical College in 1879. In that year he entered practice in Lincoln, Neb., a town of 3,000 in the midst of a prairie. Conditions were primitive—surgery was in the attics of homes, medicines and appliances were scarce. In 1883 he was instrumental in the establishment of the medical school of the University of Nebraska at Lincoln, becoming dean of the college and professor of anatomy and clinical surgery. In 1887 the school was moved to Omaha.

Since 1879 Dr. Mitchell had practiced continuously at Lincoln. He served as president of his county and state medical societies and for many years as surgeon of St. Elizabeth's Hospital. In 1920 the profession of Lincoln honored him with a doctorate in the honor of his fifty years of practice. He was surgeon general of the Nebraska National Guard during the Spanish American War and served on the Nebraska Medical Advisory Board during the World War. He was consulting surgeon to several railroads and medical director of the Farmers' Life Insurance Company. Dr. Mitchell also served as president of the American Association of Railway Surgeons.

In 1908 and again from 1910 to 1916 Dr. Mitchell was an active member of the House of Delegates of the American Medical Association, representing Nebraska. In 1916 he was elected a member of the Board of Trustees and was reelected in 1919, 1922, 1925 and 1928.

The work of Dr. A. R. Mitchell for the American Medical Association was marked by an intense quality. He gave of himself to the fullest, particularly during recent years, when he came frequently to meetings of the executive committee. During the regular sessions of the Board he was active in discussion, invariably demanding exacting medical teaching in medical affairs. He represented the best type of physician of the old school, keeping abreast of medical progress and moving fast to the traditions of the profession.

Emil Sebastian Geist & Minneapolis, University of Minnesota College of Medicine and Surgery, 1910, studied in Paris, Breslau and Vienna, 1911-1914, secretary of the Section on Orthopedic Surgery, 1913-1917 and chairman, 1918-1919, American Medical Association, associate professor of orthopedic surgery at his alma mater and the University of Minnesota Graduate School of Medicine, member of the American Orthopedic Association and the Clinical Orthopedic Society, fellow of the American College of Surgeons, major in the medical reserve corps of the U. S. Army, 1915-1918, member of the staffs of the Northwestern, St. Mary's, Sweden and Asbury hospitals, orthopedist to the Gillette State Hospital for Crippled Children, St. Paul, aged 55; died, May 14, of heart disease.

William Gray Schaeffer & Princeton, N. J., College of Physicians and Surgeons in the City of New York, Medical Department of Columbia College, 1889, past president of the Medical Society of New Jersey, member of the American Climatological and Climatological Association, professor of physiology and diseases of women, medical department, American University of Beirut, Syria, 1891-1895, served during the World War, medical adviser to the Princeton Theological Seminary

member and past president of the state board of education, aged 69, died, April 30, of cerebral hemorrhage.

Henry Kurtz Baumgardner Hafford & Major M. C., U. S. Army, San Francisco University of Pennsylvania School of Medicine, Philadelphia, 1916, served during the World War entered the medical corps of the U. S. Army as a first lieutenant in 1917 and in 1918 was promoted to major, fellow of the American College of Surgeons, aged 42, chief of the orthopedic service, Letterman General Hospital, where he died, May 5, of heart disease.

Martin Dewey, New York, Rush Medical College, College of Physicians and Surgeons, 1904, also a dentist, an Associate Fellow of the American Medical Association, past president of the American Dental Association, editor of *A Review of Orthodontia* and formerly editor of the *International Journal of Orthodontia*, aged 52, died suddenly, Mar. 14, of angina pectoris.

Albert Edward Brownrigg, Sheridan, Wyo., Baltimore Medical College, 1897, Harvard University Medical School, Boston, 1898, member of the American Psychiatric Association and the New England Society of Psychiatry, served during the World War on the staff of the Veterans Administration Hospital, aged 60, died, Mar. 3, in St. Joseph's Hospital, Nashua, N. H., of carcinoma of the lungs.

Edward Chaloupka, Omaha, John A. Creighton Medical College, Omaha, 1905, associate in gynecology, 1913-1916, instructor, 1916-1917, professor, 1923-1924, and since 1924 professor of gynecology and obstetrics at his alma mater attending gynecologist and obstetrician to the Creighton Memorial and St. Joseph's hospitals, aged 53, died, May 2, of chronic myocarditis.

Royal Charles Rodecker, Mercer Wis. Bennett College of Eclectic Medicine and Surgery, Chicago, 1898, member of the State Medical Society of Wisconsin, past president of the Wisconsin State Board of Medical Examiners; served during the World War, aged 57, was found dead in his garage, April 29, of heart disease.

Henry Exum Austin & Coatesville, Pa., Jefferson Medical College of Philadelphia, 1912, member of the American Psychiatric Association and the New England Society of Psychiatry, served during the World War on the staff of the Veterans Administration Hospital, aged 45, died, Mar. 9, of heart disease.

Charles Norris Cowden, Nashville, Tenn.; Vanderbilt University School of Medicine, Nashville, 1885, member of the Southern Surgical Association, fellow of the American College of Surgeons, on the staffs of St. Thomas Hospital and the Nashville General Hospital, aged 68, died, April 20.

John Gordon McCrummon, Detroit, Ohio State University College of Medicine, Columbus, 1928, formerly instructor in bacteriology at his alma mater, on the staff of the Henry Ford Hospital, aged 35, died, April 29, in Boston, of injuries received when struck by an automobile.

Marion Eaton Spurgeon & Red Bird, Mo.; Beaumont Hospital Medical College, St. Louis, 1901, president of the Gasconade-Maries-Osage Counties Medical Society, aged 54, died, May 7, in the Barnes Hospital, St. Louis, following an operation on the gallbladder.

Charles Elmer Brown, Rossville, Ill., Bennett College of Eclectic Medicine and Surgery, Chicago, 1895, Northwestern University Medical School, Chicago, 1903, aged 64, died, Mar. 1, in the Lake View Hospital, Danville, of septicemia and prostate abscess.

ALBERT R. MITCHELL, M.D., 1856-1933

James Edward Crichton, Seattle, University of Buffalo School of Medicine, 1883, member of the Washington State Medical Association, for sixteen years member of the city council, formerly health officer of Seattle, aged 70, died, March 20

Anson A Smith, Muskegon, Mich., Victoria University Medical Department, Coburg, Ont., Canada, 1889 member of the Michigan State Medical Society, formerly health officer of Muskegon, on the staff of the Hackley Hospital, where he died, March 31

William Clarence Upham, Washington, D C. Howard University College of Medicine Washington, 1888 member of the Medical Society of the District of Columbia aged 78 died, April 27, in the Garfield Hospital, of arteriosclerotic heart disease.

Joseph Bascumb Kirk, Bluefield, W Va., College of Physicians and Surgeons, Baltimore 1886, member of the West Virginia State Medical Association, served during the World War, aged 69, died April 19, of heart disease

Ambrose McChesney Brown, Dwight, Ill., University of Pennsylvania School of Medicine, Philadelphia, 1920, on the staff of the Veterans' Administration Hospital, aged 38, died, April 7, of an overdose of a sleeping potion

Hjalmer Melanchton Berge, Everett, Wash. University of Minnesota Medical School Minneapolis, 1921, formerly county health officer, aged 37, died April 10, in the Laurel Beach Sanatorium, Seattle of tuberculosis

Ella Merry Hasty, Minneapolis, College of Physicians and Surgeons, Medical Department of the University of Southern California, Los Angeles, 1912, aged 49, died, April 17, of carcinoma of the breast with metastasis

Ralph Leavitt Macfarland, Jamaica, N Y New York Homeopathic Medical College, 1885, member of the American Radium Society, aged 69 died, May 5, of cerebral hemorrhage, diabetes mellitus and arteriosclerosis

Wesley Reid Putney, Lake City, Fla., University College of Medicine, Richmond Va., 1912, served during the World War, aged 45, died, May 2, in the Veterans' Administration Hospital, of cerebral hemorrhage.

Robert Lee Ramey, El Paso, Texas University of Maryland School of Medicine Baltimore, 1892, fellow of the American College of Surgeons, attending surgeon to Hotel Dieu, aged 63, died, March 31

James Alexander Campbell, St. Louis, Homeopathic Medical College of Missouri, St. Louis 1869, fellow of the American College of Surgeons, aged 86, died suddenly, April 18, of chronic myocarditis

John Morgan Crane, Addison, N Y, Eclectic Medical College of the City of New York, 1901 aged 58 died, April 11, of acute dilatation of the heart and injuries received in an automobile accident

Ivan Lester Biggs, Fostoria, Ohio, Starling-Ohio Medical College, Columbus 1910 served during the World War, aged 45, died, April 29 in the University Hospital, Columbus, following a splenectomy

William James, Dover N J, University of Pennsylvania School of Medicine Philadelphia, 1906 served during the World War, aged 51, died April 20, of injuries received in an automobile accident

Samuel J Blackman, Harrisburg, Ill., Marion-Sims College of Medicine, St. Louis, 1896 member of the Illinois State Medical Society, aged 69 died, April 28 in the Lightner Hospital, of asthma

Arnold A Perry, Overland, Mo., Barnes Medical College, St. Louis, 1900 formerly coroner of St Charles County aged 61 died, March 4, of septicemia, following tooth extraction ten days previously

Israel James Clarke, Haverhill, Mass., University of the City of New York Medical Department, 1884, aged 72, died, May 4, in the Gale Hospital, of arteriosclerosis and arteriothrombosis

Alfred Herbert Vogt, Albuquerque, N M., University of Buffalo School of Medicine, 1916, member of the New Mexico Medical Society, aged 41, was found dead in bed, April 1, of heart disease.

Peter Aloysius Slattery, Cedar Rapids, Iowa, John A. Creighton Medical College, Omaha, 1908, member of the Iowa State Medical Society, aged 57, died, April 16, of cerebral hemorrhage.

Robert Percy Crookshank, Brandon, Manit., Canada, College of Physicians and Surgeons in the City of New York, Medical Department of Columbia College, 1878, aged 81, died, February 2.

Thomas W Cross, Birmingham Ala University of Nashville (Tenn.) Medical Department, 1877, aged 85, died, May 3 in the Norwood Hospital, as the result of an injury received in a fall

George B Twitchell, Cincinnati, Miami Medical College, Cincinnati, 1891, aged 68 died, April 27, in the Jewish Hospital, of carcinoma of the base of the tongue and myocarditis

William Charles Pontius, Warren, Ohio, Temple University School of Medicine, Philadelphia, 1917, served during the World War aged 46, died, May 3, of bronchopneumonia.

Louis Textor Boyer, Steubenville, Ohio, University of Pittsburgh School of Medicine, 1923 aged 34, died April 30, in the Mercy Hospital, Pittsburgh, of agranulocytic angina

Frederick Olin Pease, Chicago Chicago Homeopathic Medical College, 1886, aged 80, died, April 17, at his brother's farm near Pipestone Minn., of cerebral hemorrhage

John Louis Marchand, Bluefield Nicaragua, Central America University of Pennsylvania School of Medicine, Philadelphia 1894, aged 64 died, April 6

Edmund Abbott, West Kingston R. I., University of the City of New York Medical Department, 1879 aged 76, died, April 12, of carcinoma of the bladder

James J. Troutt, Nashville, Ill University of the City of New York Medical Department 1872, aged 88, died, April 24, of carcinoma of the right testicle

Frederick John Schnell, North Tonawanda, N Y, Baltimore Medical College 1905, aged 56, died suddenly, May 5, of coronary heart disease.

Joseph Cinq-Mars, St. Sacre Coeur de Marie, Que., Canada Laval University Faculty of Medicine, Quebec, 1885, aged 70, died February 27

Lucius A Wright, Los Angeles, Physio-Medical Institute, Cincinnati 1876, aged 81 died, April 8 of coronary thrombosis and cerebral embolus

Thomas Crandel, Warren, Ind Eclectic Medical Institute, Cincinnati, 1869, Civil War veteran, aged 95, died, May 6 of lobar pneumonia

Granville Corwin McCreight, Willard, Ohio Miami Medical College, Cincinnati, 1901, aged 60, died April 22, of arteriosclerosis

David Nathan Bloom, Boston Baltimore University School of Medicine 1904, aged 62, died, May 3, of cardiovascular disease.

Samuel B Koser, Sebring Fla Baltimore Medical College, 1891, aged 67, died, April 9, of chronic myocarditis and arteriosclerosis

William R Pennington, St Joseph, Mo College of Physicians and Surgeons, Chicago, 1898 aged 76, died, January 17

Everett Riley Beard, Liberty Ind., Medical College of Ohio, Cincinnati, 1897, aged 62, died, April 28, of coronary thrombosis

Eugene William Pape, San Francisco University of Nebraska College of Medicine, Omaha, 1926, aged 30, died, January 9

Worth A Thompson, Rutherfordton, N C., College of Physicians and Surgeons, Baltimore, 1885 aged 70, died, February 28.

Leonard A Bratholdt Minneapolis Rush Medical College Chicago, 1905 aged 55, died, April 16, of heart disease

Thomas G Ashton, Wynnwood, Pa., Jefferson Medical College of Philadelphia, 1888, aged 65, died, February 23

Thomas Leroy Hickman, Findlay, Ohio (licensed, Indiana, 1897), aged 78, died, March 7, of heart disease.

Marriages

REGINALD MICHAEL NORRIS, Jacksonville, Ill., to Miss Mary Schultz of Beardstown, April 24

VAN BUREN MAURICAU Morton, Ill., to Miss Frances Kraemer of Joliet, April 22

CHESTER C DOHERTY, Chicago, to Miss Bernadine Flynn of Madison, Wis., April 29

R. FRANCIS ETIENNE to Miss Jane Elizabeth Lynch, both of Akron, Ohio, April 25

RAYMOND S SIMENSON, Chicago, to Miss Violet Starks of Madison, Wis., April 22

THE W O BYE CANCER CURE

Still Operating from Kansas City, Mo

William O Bye of Kansas City, Mo., has long been in the advertising "cancer cure business." He was born in 1870 and holds a diploma issued in 1897 from Bennett College of Eclectic Medicine and Surgery. Associated with him for the past few years has been one Arthur Heinzelmann, who holds a diploma issued in 1907 from the Eclectic Medical University of Kansas City, a low-grade school that went out of existence some years ago. In 1912 Heinzelmann's name appeared as superintendent of a "cancer cure" concern, the Cliff View Sanatorium of Kansas City, Mo., which advertised the escharotic treatment of cancer.

William O Bye for many years operated his "cancer cure" through the mails, but the postal authorities in 1910 declared this business a fraud and debarred it from the United States mails. William O Bye is a brother of Benjamin F Bye, both sons of another old offender D M Bye, all of whom together with Leon T Leach, son-in-law of D M, used to operate mail-

Book on Cancer Free

When hundreds of perfectly reliable people gladly testify that they have been rescued from death's door by Dr Bye's Combination Oil Treatment for Cancer and similar dreadful diseases, it is surely worth while to investigate the methods and results of this treatment. Any one may obtain free of charge a finely illustrated book describing this simple and efficacious treatment, simply by writing Dr W O Bye Ninth and Broadway, Kansas City, Mo.

CANCER its successful treatment with out use of the knife. Hundreds of satisfied patients testify to this mild method. Write for free book. Tells how to care for patients suffering from cancer. Address Dr W. O. Bye, Kansas City Mo.

Above, one of W O Bye's older advertisements. Below a 1933 advertisement.

order "cancer cures." All four of these gentry claimed to have alleged "oil treatments" for the cure of cancer. When the postal authorities got around to W O Bye and the federal chemists analyzed the no-trums comprising his treatment, it was reported to consist of five different preparations: (1) A mixture of cottonseed oil and almond oil; (2) a product resembling syrup of sarsaparilla; (3) sugar pills; (4) vaseline and (5) a clay poultice.

W O Bye in his old mail-order advertising claimed that he had "an intallible cure for all forms of cancer" and that he had effected cures in some of the worst cases of internal cancer. In 1907 W O Bye's license to practice medicine in Missouri was revoked by the Board of Health of that state, but Bye appealed to the courts submitting depositions from those he claimed to have cured of cancer. The court ordered the Board to restore his license. The postal authorities later showed that the depositions that Bye had presented were, in most instances from individuals whose alleged cases of cancer had never been diagnosed as cancer at all!

Following the issuance of the fraud order against W O Bye, he, in common with other mail-order "cancer cure" concerns, modified his method of doing business by requiring his patients either to come for a personal examination and diagnosis or to have a local physician fill out a card that Bye would furnish stating that the patient had cancer. An Indianapolis physician

reported in 1932 the case of a patient of his who was dying of cancer of the cervix and having seen one of W O Bye's advertisements, wrote to Bye. Bye replied to the poor woman as follows:

"I have your letter and in reply will say before furnishing you treatment, I would first like to make an examination of your case, if possible, in order to get a good understanding of it and to prepare treatment accordingly. If desired I will agree to come there, to your home examine you and furnish a month's treatment for \$100.00 and the expenses of the trip money to be paid while there. Expenses means railroad fare both ways, sleeper meals etc. en route. This price includes the first month's treatment price, thereafter should more be needed to be \$30.00 per month for treatment. After examination I can give all information desired. I will bring the medicine along prepare and leave one month's supply at no extra charge, with full directions, so you can use it yourself."

Bye has for years sent out an advertising booklet entitled "A Message of Hope." In this he leads the recipient to believe that operations and the use of x-ray and radium in the treatment of cancer should be avoided. The booklet contains testimonials from persons who are alleged to have been cured of cancer by W O Bye. The edition issued in 1933 is less than half the size of that issued ten years previously—forty-eight pages as compared with one hundred and one pages. The 1922 edition of "A Message of Hope"—which, by the way was from the "Press of the Western Baptist Publishing Co., Kansas City, Mo."—reproduced among other testimonials what purported to be "before and after" pictures of three women who were said to have been cured of cancers of the face. To any one familiar with photographic processes it was obvious that in each case the pictures used to show the patient "after" the growth had been removed were made from the same negatives as the "before" pictures, the engraver or photographer having skillfully removed the growth with a retouching pencil!

While the present day newspaper advertising deals only with Bye's cancer "cure," it appears from "A Message of Hope," pamphlets now being sent out that he is willing to turn his talents to the treatment of Gastric Ulcer and "Skin Diseases." He used to extend his specialties to include, also, Chronic Nasal Catarrh, Rectal Diseases, "Female Diseases" and Uterine Displacement.

W O Bye still advertises. The recent advertisement reproduced with this article appeared in the January, 1933, issue of one of those cheap publications that seem to depend for their existence on the revenue from advertising so rotten that it would be rejected by magazines and newspapers that had ethical standards.

In Bye's Message of Hope sent out in March, 1933, he makes this statement about the character of his treatment:

Our treatment is both local and constitutional in all cases and is prepared especially for each individual. The local remedies are applied directly to the affected parts in the form of oils (italics ours—Ed.), ointments, powders, pastes, liquids and injections.

From this it would seem that the "oil treatment" still persists.

Correspondence

"THEELIN"

To the Editor—The report of the Council on Pharmacy and Chemistry on "Theelin" (THE JOURNAL, April, 29) fails to stress one serious danger arising from the careless administration of this substance.

Many, it is not most, of the disturbances of the female sexual cycle are psychogenic in origin and all such disturbances must have psychic implications. Dysmenorrhea is extremely common in neurotic women, especially in those who have taken refuge from unconscious sexual conflicts by establishing psychic frigidity.

Any medicament which tends to increase the somatic sexual urge in such women (and several observers agree that an increase of libido is an effect from "Theelin") must obviously intensify the conflict which is already almost unbearable. When a woman is already struggling against unadmitted autonomic

cravings and, by dint of psychic frigidity and various functional disturbances has succeeded in establishing an uneasy and partial adjustment, the exhibition of an agent that increases such autonomic cravings must make things worse—and often does, quite obviously. Serious panics, even major psychoses and suicidal attempts not infrequently follow the injudicious use of 'Theelin' in such cases.

I have myself observed a number of such untoward reactions and so have many others—though they may not have understood or admitted the causation.

Let me repeat 'Theelin,' and all other female sex hormone preparations and other therapeutic agents which do or may, increase somatic sexual desire, must be used only with great caution if at all in neurotic women. To increase autonomic cravings which are already the cause of intrapsychic conflict, and which have been rejected as inadmissible by the ego, is dangerous, and may (and often does) break down the patient's resistances and thus precipitate psychosexual panic, frank insanity or suicide.

Until the patient's psychic resistance to the libido is overcome by suitable psychotherapeutic means any increase in somatic libido is contraindicated.

ERNEST M. POATE, M.D., Southern Pines, N. C.
Associate Professor of Psychiatry, Duke
University School of Medicine.

THE FETISH OF TRIPLY DISTILLED WATER

To the Editor—In answer to the communication by Elser and Stillman we wish to submit the following data, which have been stressed in our recent article on the 'Prevention of Chills Following Transfusion of Citrated Blood.' Our paper refers mainly to the various factors which were found from experience to be of extreme importance in the prevention of chills following transfusions. In our hands single distilled and doubly distilled water were found to be ineffective in the prevention of chills for citrate transfusions. The best results were obtained only with triply distilled water.

We have also stressed the importance of the preparation of the instruments in the central supply room, the slow infusion, and the mutual tests prior to transfusions.

The problem concerning the use of intravenous saline solution and dextrose is somewhat different. The number of chills following the administration of such substances is considerably less than the number of those following citrate transfusions irrespective of the nature of the distilled water. With respect to these fluids however, our results have also been considerably better, since we have been using triply distilled water.

RICHARD LEWISOHN, M.D.
NATHAN ROSENTHAL, M.D.
New York.

USE OF COBRA POISON THERAPEUTICALLY

To the Editor—In glancing through the April 29 issue of THE JOURNAL, under the section devoted to foreign letters, I noted a paragraph relating to the treatment of cancer with cobra poison. In this paragraph it is indicated that Mr. Korošios and Mr. Laignel-Lavastene had made the original research in this direction. May I suggest that as far as I am aware, it was a New York physician who originally studied the effect of snake poisons in treating certain diseases, including cancer, his work being steadily conducted for the past six years. At his request I extracted and tendered cobra (*Naja*) and *Crotalus* venoms to him during this period, and assisted him in his laboratory with the preparation of the modified

cobra poison for injection. Until about a year ago, he steadily supplied Dr. Gosset and Dr. Taguet of Paris with the modified cobra poison with which they conducted their experiments at the Salpêtrière Hospital in France. Recently Professor Calmette prepared some of the solution from the formula given to him by the New York physician. I also assisted in necropsies on the animals which this physician used in his laboratory in connection with his experiments with cobra venom injections.

In 1929, I received an invitation and attended a meeting of the staff of St. Elizabeth's Hospital in New York where the results of several years of this work were reviewed.

Several physicians in this country and in Canada have also used the modified cobra venom prepared by the New York physician.

Reptiles, New York Zoological Park.

GLIOMA OF THE RETINA

To the Editor—The newspaper notoriety given to the Vasco case—the child whose parents refused operation for a tumor of the retina—brings up several questions. If surgery fails, the irregulars and the general public perhaps will say that here scientific medicine stepped in at the behest of the law and yet the life of the child was not saved.

Glioma of the retina is a terrible disease and demands primarily brain and not eye surgery. When it kills, it does so practically always by direct extension of the tumor backward through the optic nerve to the brain. The surgical problem, then, is always to remove all the nerve possible.

The optic nerve is 5 cm. long, of which 3 cm. is in the orbit, 1 cm. in the bony optic canal and 1 cm. intracranial (Norris and Oliver, vol. 1, p. 386). The usual procedure among eye surgeons (of whom I happen to be one) is to enucleate the eye and, if the cut end of the nerve shows disease or if a local recurrence occurs later the orbital cavity is cleaned out down to bone. This exenteration of the orbit gets all the tissues and of course, all the nerve within the orbit. However it leaves 2 cm. of the nerve between the orbit and the chiasm.

Two British investigators (N. M. Dott and Spence Meighan) reported before the Ophthalmological Society of the United Kingdom at Edinburgh in May, 1932 that they had resected successfully the optic nerve intracranially up to the chiasm for glioma of the retina in a child in whom, after enucleation, infiltration of the tumor was found at the point of section of the optic nerve. They were led to do this because in about half of all cases of enucleation for glioma of the retina, the section through the nerve of an enucleation is not in sound tissue as shown by A. B. Reese. This British report seems to be the first intracranial removal of the optic nerve in glioma on record.

Two eminent brain surgeons in personal communications (I do not feel at liberty to call their names) assure me that the mortality in performing an intracranial operation for the removal of that portion of the optic nerve from the chiasm on forward through the canal in the hands of properly qualified surgeons should be very small. One states 'two per cent or thereabouts' and the other surgeon strongly insists that the risk of an intracranial operation is increased tremendously if the eye has been removed previously because of 'the possibility of coming in contact with the infected stump in the back of the orbit.' He also states that, if the eyeball has not been removed the danger remains slight. What a warning to eye surgeons to keep out!

In 1922, in a discussion of glioma retinae I said 'It seems advisable that brain surgeons should attack these cases from within the brain, which they can do with reasonable safety' (*Arch. Ophth.* 51:505 [Sept.] 1922). In 1925, in London at

the Ophthalmological Congress, in discussing a case of glioma of the retina with extension of the tumor backward beyond the optic foramen (roentgenograms of the optic canal in this case showed enlargement and therefore most certainly extension into the canal), I suggested that "the operation for its removal often came within the province of the brain surgeon and not the ophthalmic surgeon." To show the fear ophthalmologists have of brain surgery, both the reader of this paper in London and the president of the society said that they would not even think of brain surgery in these cases (*Tr Ophth Soc U A*, 45, 1925).

Let the ophthalmologist diagnose the glioma. Let him assure himself that the second eye is not involved, since that raises other problems (would the law have ordered the removal of both eyes in the Vasco child?) Let him order a roentgenogram of the optic foramina. Then let the ophthalmologist turn the case over to the brain surgeon for operation and not destroy the child's chance of life by trying enucleations, orbital exenterations, radium and what not.

GEORGE W. JEAN, M.D., Santa Barbara, Calif

THE LIFE CYCLE OF THE TUBERCLE BACILLUS

To the Editor—In *THE JOURNAL*, April 29, page 1342, is a brief review of our studies on the tubercle bacillus (Mellon, R. R., Richardson, R. D., and Fisher, L. W. *Proc Soc Exper Biol & Med* 30 80 [Oct.] 1932; Lindgren, C. C., and Mellon, R. R., *ibid* 30 110 [Oct.] 1932; Mellon, R. R., Richardson, R. D., and Fisher, L. W. *J Bact* 24 45 [Jan.] 1933). I feel sure that the reviewer did not intend to leave the impression that we had postulated the existence of morphologically distinct male and female sex cells. But since this impression has been conveyed to me from others permit me to interpret these studies as follows. The sexual mechanism suggested (not proved) is that of an autogamous fusion (Lindgren, C. C., and Mellon, R. R. *J Bact* 25 47 [Jan.] 1933), one of the lowest orders of sexuality, in contrast to a true bisexuality, which is the highest order. Biologically the implications of the two types differ so much that I should not wish the critical reader to gain a wrong impression.

Moreover, even this suggestion has the status of a theory rather than a fact. Its latest support is our demonstration of special nuclear structures strikingly similar to that existing in the sex cells of the fungi and by cytologic technic regarded as definitive for nuclear material. Standing alone it is indeed surprising that certain stages in the life history of a bacterium should have such structures, particularly when a nucleus as such has never been accepted for the bacterial cell. Yet we feel that such evidence is inadequate on which to base conclusive claims for sexuality. We do view it as an advance in this direction carrying us farther to that goal—if, indeed, one exists.

But I also wish to make clear that the sum total of our recent evidence for a life cycle of the tubercle bacillus depends in no way on the validity of the conception just discussed, unless of course one would limit life cycles to those of sexual nature. Briefly, this evidence is, first, that the well known filtrable granules (of Much?) give rise to non-acid-fast diplococci, diphtheroids, and so on; secondly, that these distinct species—so called—may revert to the nonvirulent, or R, form of the tubercle bacillus, and, thirdly, that the latter can be forced back to the S, or virulent, form from which the granules of Much are obtained.

This is tantamount to saying that all the principal variants (or mutants?) that have been described for the tubercle organisms since Koch's time are seen to be stages in a cycle, in the

sense that ultimately they are capable of reversion to the original tubercle bacillus. Moreover, the experimental animal with its hazards for variability work is not an essential part of the evidence.

Director, Institute of Pathology, Western
Pennsylvania Hospital

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address but these will be omitted on request.

PROBABLE DIAGNOSIS OF THROMBOCYTOPENIC PURPURA

To the Editor—A white girl, aged 11, first noticed a fine macular eruption about the ankles March 27, 1933. This eruption gradually spread over the entire lower extremities. There was no itching pain or systemic disturbances. The spots came out quickly and consisted of pinhead to pea sized round oval and irregular claret red spots which did not fade on pressure. At present the eruption is brownish and disappearing. About April 4 she noticed a tenderness and weakness in both calves, and two or three days later the right hips became swollen, tender, red and hard. About the time of muscular symptoms she began complaining of sudden attacks of cramplike pain about the umbilicus. There was vomiting for two or three days following meals from half an hour to two hours. At present there is a swelling of her forehead and occipital region with some pain and tenderness. There is no history of easy bruising or prolonged bleeding and there is no blood in the urine, feces or vomitus. Birth and infancy were normal. She had a severe illness at 4 years of age which a doctor called dropsy. Enormous swelling of the extremities and the abdomen at this time lasted only one week. She has had measles and whooping cough. At present there is nocturia of from one to two times. One crude urinalysis was negative. Blood count was not done. She has one brother and six sisters living and well. Both parents are in good health. Her temperature, April 10, was 98.8 at 11 a. m., the pulse was 76 and the blood pressure was 95 systolic, 64 diastolic. The eyes, ears, nose and mouth appear to be not diseased. No abnormality was identified in the lungs or heart. No enlargement of the liver or spleen was made out. There was no tenderness in the abdomen. The reflexes seemed normal. Please suggest diagnosis and treatment. I realize that there may be much lacking in this case report but one doing contract practice in a coal mining camp is used to much lacking. M.D. Kentucky

ANSWER—All the symptoms described may be explained as caused by hemorrhages. The statement that there was no blood in the urine, feces or vomitus must be accepted as meaning that no blood was noticed. The case is one of mild purpura. A blood examination, including a differential count of the white cells and a platelet count, is the first requisite, to decide whether this is a thrombocytopenic case or belongs among the nonthrombocytopenic forms. If the platelets are low, 100,000 or less, it belongs in the first category, either as morbus maculosus of Werlhof or one of the many forms of symptomatic purpura.

In the case under discussion, Werlhof's disease seems to be ruled out by the mildness of the symptoms and the absence of splenic enlargement. The clinical examination has also eliminated Hodgkin's disease, tumors, sepsis, endocarditis, icterus and other infectious processes that might be responsible for the purpura. The blood count will rule out the severe anemias and leukemia. There remain the effects of heavy treatment with roentgen rays or radium, avitaminosis and anaphylaxis.

If the platelet count, coagulation time and bleeding time are about normal, the case belongs in the second category. Schoenlein's disease, purpura rheumatica, can be ruled out because of the afebrile, nonarthritic course. The visceral symptoms described suggest that this may be a mild case of Henoch's purpura, which occurs often in children, may clear up in a short time and never recur, or may recur from time to time, like erythema multiforme, with which it is often associated. The case should be studied further, the temperature recorded several times a day, the heart examined repeatedly, and a careful urinalysis made at intervals. If visceral symptoms recur, the excretions should be saved for inspection by the physician and, if necessary, for laboratory examination.

Whatever form of purpura may be decided on, the patient should be kept in bed. If recovery does not progress smoothly, calcium may be given, either by mouth, 1 or 2 Gm. with an equal amount of lactose dissolved in a half glass of hot water after each meal or calcium gluconate intramuscularly. In

cases not due to arsenicals, arsenic pushed to the physiologic limit is beneficial, particularly in children. Ultraviolet ray baths, roentgen therapy applied to the spleen, and intramuscular injections of whole blood or blood serum from a healthy individual are recommended.

After recovery, the child should be watched and studied for indications of infection or of allergy.

INFECTIOUS ECZEMATOID DERMATITIS

To the Editor—A woman aged 30 unmarried has been ill for four months. She does office work. She has had severe prolonged attacks of articular rheumatism and a considerable amount of fluid has been taken from the knee joints. She had a large ovarian cyst removed when she was in her teens. Tonsillectomy seemed to help the rheumatism. For several years she has had a dark patch on her left shin just above the ankle, about 6 inches long. Six months ago the same kind of spot appeared on the right leg. This gave her no trouble but the appearance was not to her liking so she consulted a competent x-ray man who, last October gave her three or four roentgen treatments followed by a quartz ray exposure. Two weeks later the skin of both legs became red enormously swollen and commenced to weep and this condition has persisted to date, becoming better and worse. The itching and burning are almost unbearable and nothing applied locally or given internally has the least effect. Shortly after the legs became swollen there appeared over the entire body including the scalp an erythematous eruption (never any fever) accompanied by terrible itching and burning with itching and burning in the rectum and vagina. At this time the eruption over the body has improved greatly and the swelling in the legs is better but the skin of both legs continues to weep. There was weeping only on the legs. Her saliva was acid for a few days. To make matters worse, four days ago several of her joints became swollen as they used to formerly. The only x-ray burns I have ever seen were in Cook County Hospital in victims of State Street quacks. There were deep sloughs. This case is different. I know the x-ray man who treated this girl and he is competent. He treats many patients and has never had a burn. Any suggestions will be appreciated.

JOHN J. MCINTOSH M.D. Mount Carmel Ill

ANSWER—The description is not that of radiodermatitis. Presumably the original patch on the leg was eczema of unknown etiology. Either spontaneously or as a result of therapeutic hyperemia the eczema became exudative. The patient then became sensitized or allergic to the exudate. The eczema would now be of the type known as infectious eczematoid dermatitis. The patient should have soothing lotions for the body eruption. Tub baths should be avoided for a while. The legs should be kept elevated and constant well applied wet dressings should be applied to the exudative eruption. The wet dressings may consist of Burrows solution diluted fifteen or twenty times with distilled water or diluted with boric acid solution. Sometimes a continuous wet dressing of 0.25 per cent silver nitrate is effective. After a week or ten days of such treatment, the following emulsion may be painted on freely and frequently: zinc oxide, 30 Gm., magnesium carbonate 30 Gm., bismuth subnitrate 30 Gm. lime liniment U S P, sufficient to make 236 cc. Cleansing should be done with either olive oil or liquid petrolatum.

AN EXPLANATION OF SENSITIVENESS FOR THE PUBLIC

To the Editor—The enclosed pamphlet by George Martyn M.D. entitled *Facts and Theories Explanatory of Sensitiveness and Its Role in Disease* written for my patients and friends is submitted for your comments. Do you regard its teachings as sound? Do you approve of this method of instructing patients actual and prospective? Please omit name.

M.D. Chicago

ANSWER—Scientifically, this booklet has a good side and yet it is also open to serious criticism. The author evidently tries to correlate theory and practice so that something useful will emerge. His description of the symptoms of migraine, hay fever and asthma are fairly good; however, he states that hay fever attacks are frequent mostly through the spring or autumn when certain groups of pollens are plentiful in flowers, dust or grass. A more accurate statement would be that hay fever occurs in spring from the pollen of trees in summer from grass pollen and in fall from the pollen of weeds. Flowers and dust per se are not important.

The description of 'intestinal colic' is most indefinite. Beyond including it as sensitization disease there is no further light thrown on the etiology. Intestinal colic is not a good title as it suggests any sort of gastro-intestinal upset associated with spasms of pain and therefore includes both allergic and nonallergic groups.

The allergic group should be clearly labeled by some such title as 'gastro-intestinal allergy' or 'food allergy' to denote that certain foods are responsible for the symptoms.

The author boldly states that arthritis and gout are due to sensitization. There is no evidence that gout belongs to the group of allergic diseases. One form of arthritis (intermittent hydrarthrosis) is probably allergic. All the other varieties of arthritis do not belong in the group in the restricted sense of the word. Arthritis is not a sensitization disease as are hay fever, bronchial asthma, hypertrophic rhinitis, food allergy and certain skin conditions. It may be a sensitization from another point of view depending on the bacteria that cause the disease. It should therefore not be included, in the present state of knowledge, under allergic diseases.

The author's theories regarding histamine are well taken, but he states them as though they were already proved. For example, he says that 'Sir Thomas Lewis's work on the reactions of the skin proves that the release of histamine and the secondary reactions therefrom is the most important part of this whole question of sensitization. It may be well to remind the author that Lewis was careful to use the word 'h-substance' and though he brought out that this substance had histamine-like properties, he did not say it was histamine. There is no doubt that there is a strong resemblance between the symptoms of anaphylaxis and histamine intoxication, but it remains to be proved that histamine causes anaphylactic shock and allergic conditions such as bronchial asthma and hay fever.

From an ethical point of view, it would probably arouse less criticism if such booklets were distributed only to patients not, as the author puts it, written for my patients and friends. There is no harm in giving each patient a booklet which will tell him something about the sickness from which he suffers and which should include general instructions with a view to mitigating the symptoms. The booklet should also have a definite place for the writing by the physician of special orders for the individual patient.

LIGNASAN AND MERCURY POISONING

To the Editor—Please give me your opinion of Lignasan which is being manufactured by the du Pont de Nemours Company. The active ingredient of this preparation is ethyl mercury chloride, which at the present time is present to the extent of 5 per cent in this compound. This is mixed with other inert substances. This ethyl mercury chloride is added to water one pound to fifty gallons of water and the timbers fresh from the saw are dipped in this solution. The presence of the ethyl mercury compound effectively prevents the growth on the surface of the boards of various stain fungi commercially known as blue stain. A great many tests have been carried out, not only by the du Pont Company but by the pathologists of the United States Bureau of Plant Industry. Ethyl mercury chloride is of course, a very volatile substance, and it rapidly leaves the surface of the boards. I have been advised by my friends of the Bureau of Plant Industry that in all probability all of it disappears in from sixty to ninety days. It has been proposed that we use this substance for the dipping of cross ties. I am somewhat hesitant about the application of this preparation owing to the nature of the active ingredient. I have consulted a number of dermatologists as well as internists on this question and they confirm my doubts. 1. What effect if any would the handling of the solution as described have on individuals who would necessarily have to handle the wet ties after dipping? By which question I mean the effect on the hands or skin or due to possible inhaling of the volatile compound. 2. Would the inhaling of the volatile compound during the process of seasoning that is during the two or three months that the evaporation of the toxic compound would take place be likely to have any effect on the men in the immediate vicinity of the piles of ties or timbers so treated? I have had a lot of experience both in Europe and in this country in the study of arsenic compounds used in the preparation of wall paper impregnated into wood and so on and I am wondering whether we might be facing the same or a similar situation in connection with this ethyl mercury compound.

CONSULTING TIMBER ENGINEER
Missouri Pacific Railroad Company St. Louis

ANSWER—The Joint Committee on Sap Stain Control working under the auspices of the Federal Bureau of Plant Industry published the following statement in December, 1932, concerning Lignasan:

In spite of the rather wide and rapid adoption of the new Lignasan treatment it was obvious that certain inherent weaknesses existed. First among its limitations is the possibility of the mercury injury attached to its use. While no cases of this type of injury have been reported to date where the treatment was used at the recommended strength, minor cases of skinburn have been encountered chiefly, however, as a result of careless handling of the powder or use of solutions stronger than those recommended. Although no great danger may exist it is obvious that the use of a nonmercurial compound in which the possibility of injury is definitely removed is more desirable.

It is obvious then that the present treatments are in need of improvement or that the search should be continued for new and more efficient treatments.

This statement implies answer to the specific questions raised in the query but may be amplified as follows:

1. It is believed that a mercurial dermatitis may arise among some unprotected workers handling wet ties after dipping.

Although the amount of mercury in the solution, as made up, is minute, rapid concentration takes place owing to the evaporation of the water leaving relatively high concentrations of mercury on the surface of the ties or lumber. This is to be expected as the direct result of contact with mercury and is not due to the inhalation of the volatile compound. It is possible that some mercury may enter the body through the skin and lead to systemic mercury poisoning. The hazard however, is not so great as from the use of corrosive mercuric chloride solution in the ordinary course of medical treatment. No exact information is known to be available.

2 The inhalation of the volatile compound during the process of seasoning may be expected to eventuate in mercurialism provided the quantity of mercury vapors is high. The daily absorption of from 0.77 to 1.29 mg of mercury is regarded as capable of inducing mercury poisoning. Consideration must be given to the likelihood that most ties will be stacked in the open air outside of buildings. Apart from the initial stacking shortly after dipping it is unlikely that practical conditions of exposure may be regarded as hazards. A simple test for mercury in the air may be found in the exposure of selenium indicator papers, which change color in characteristic fashion in the presence of mercury. Such test papers may be procured from any large chemical supply house.

It is not known that this test has been applied to vapors of organic mercury compounds so that the foregoing statement is an assumption based on experience with inorganic mercury compounds.

A good discussion of mercury poisoning from minute quantities of mercury vapors may be found in an article entitled *Mercurial Poisoning. A Report of Poisoning From Small Quantities of Mercury Vapor* by J. A. Turner (*Pub. Health Rep.* 39:329 [Feb. 22] 1924). Extended information may be procured from G. N. Harrison, Executive Officer Joint Committee on Sap Stain Control, Federal Bureau of Plant Industry, Washington, D. C.

DROOLING OR PTYALISM IN CHILD

To the Editor—Please advise me regarding the treatment of drooling in a 2 year old boy. This symptom has been present since the age of 4 months. The eruption of the teeth has been regular. The drooling has not been affected in any way by the eruption of the teeth. There is no apparent pathologic condition in the mouth. At present there is almost a continuous flow of saliva from his mouth. This causes a severe irritation of the skin over his chin and wets his clothing.

C. E. JOHNSON, M.D., St. Paul

ANSWER.—Drooling, or ptyalism, is the term employed to denote excessive secretion of saliva. However, in a given instance it may be difficult to determine whether there is actually an increased secretion or whether a normal amount of saliva is being allowed to drool from the corners of the mouth. In some instances the difficulty is simply one of swallowing the normal secretion, for example in infancy and in bulbar paralysis, in mercurial stomatitis there is increased salivation, besides difficulty in swallowing, and in certain functional or hysterical cases there is excessive secretion with no difficulty in swallowing. The latter condition has been termed 'ptyalorrhea'. It should be remembered that the mouth in early infancy tends to be dry and the tongue is also dry and is generally covered with a whitish coating. This dryness of mouth and tongue is due to the small amount of saliva excreted by the new-born. Salivary secretion becomes more active by the second month of life, and by the fourth month the secretion is usually well established and the infant drools. At this period diastasic activity first becomes appreciable and from the fourth month to the end of the first year the amount of saliva becomes greater and its diastasic properties increase correspondingly. The eruption of teeth appears to be in no way connected with the amount of salivation.

The secretion of the salivary glands is influenced by nervous stimuli from the chorda tympani nerve, a branch of the facial nerve, and also by cervical sympathetic nerves from the superior cervical ganglion. These nerves carry not only secretory but also vasomotor fibers. Therefore there are secretory fibers from cerebral innervation, and trophic fibers of sympathetic origin regulating salivary secretion. In the case in question if the various drugs are eliminated that may cause excessive salivation when taken internally or applied externally, if no form of stomatitis is present and if there is no difficulty in swallowing a normal amount of saliva due to local lesion or pseudobulbar paralysis the excessive secretion must be considered due to reflex stimulation.

Local reflex irritation of the fifth nerve may be caused by a jagged tooth, a foreign body as a fishbone impacted in the

gum, a ranula, a salivary calculus, or an irritation produced by a corrosive substance or recent injury. Other reflex influences, as nausea, gastritis, dyspepsia and gastric ulcer, may cause excessive salivation. Lack of proper cerebral control causes the drooling noted in imbeciles, idiots and other mental patients. Finally a purely functional cause of excessive salivation must be assumed. If the various physical and reflex causes for the drooling in the case in question can be ruled out, the condition is probably an excessive physiologic secretion in a young child, which will tend to correct itself. Various greases or salves to protect the skin of the chin may prove helpful, as well as a bib or a frequent change of clothes.

HIBBS OPERATION FOR SPINAL FRACTURE

To the Editor—Can you tell me where I may secure the detailed technique of the Hibbs operations for spinal fracture?

P. D. McLEOD, M.D., Tonopah, Nev.

ANSWER.—The technic for the Hibbs operation for spinal fracture is similar to the technic he described for fusion of the spine in cases of tuberculosis of the vertebrae. This is given as follows by Hibbs:

An incision is made through the skin and subcutaneous tissue, exposing the tips of the spinous processes of the vertebrae to be fused. By means of special periosteal elevators, the spinous processes the posterior surfaces of the laminae and the bases of the transverse processes are bared of periosteum. Gauze packs are inserted to prevent oozing.

The ligamentum subflavum is removed from the laminae with a curet, and the articulation of the lateral processes is destroyed in order to establish a bone contact at this point. With a bone gouge a substantial piece of bone is elevated from the adjacent edges of each lamina, of half its thickness and half its width. The free end of the piece from above is turned down to make contact with the lamina below and the free end of the piece from the lamina below is turned up to make contact with the lamina above.

Each spinous process is then partially divided with bone forceps and broken down forcing the tip to come into contact with the bare bone of the vertebra below. Thus is established contact of abundant cancellous bone at the articulations of the lateral processes laminae and spinous processes. The periosteum and ligaments which together have been pushed to either side and lie practically as an unbroken sheet, are brought together in the middle with interrupted sutures of ten-day chromic catgut. The subcutaneous tissue is then closed with a continued suture of plain catgut, the skin wound is closed with sutures of ten day chromic catgut, and sterile dressings and an immobilizing brace or removable plaster cast are applied.

OXYGEN IN PNEUMONIA

To the Editor—In the use of oxygen in the treatment of pneumonia 1. What is the danger of too great a concentration of oxygen? 2. Is there danger in continuing the use of oxygen after the period of oxygen want has been passed? Please omit name.

M. D. Minnesota.

ANSWER.—1 Numerous observations on animals since the time of Paul Bert (1878) have shown that high oxygen concentrations were injurious to the lungs and some of the other organs. (References to this phase of the literature are given by Boothby on page 2107 of his article on oxygen therapy in *THE JOURNAL*, Dec. 10, 1932, p. 2026 and Dec. 17, 1932, p. 2106.) With increased oxygen concentrations of less than one atmosphere (760 mm. or 100 per cent) and above 70 per cent the chief deleterious effect is directly on the pulmonary tissue, causing congestion and edema. The pulmonary epithelium frequently desquamates. Actual pneumonia is often produced. The lungs of some animals are more susceptible than are the lungs of other animals to injury by an increased oxygen concentration. It may be that under certain conditions some human lungs may be more sensitive to injury by excessively high oxygen concentrations than are others.

While no one has demonstrated harm to human individuals from concentrations of 80 or 90 per cent, it is inadvisable to use concentrations for any length of time above 60 per cent, as above this concentration the pulmonary tissue of some animals is definitely injured and in some instances a fatal pneumonia is produced. Concentrations up to 60 per cent at sea level (450 mm.) can be considered safe.

2 There is no danger in continuing the use of oxygen after the period of oxygen want is passed, on the other hand, there is no advantage in so doing except for a short period while in doubt about whether or not oxygen is still needed.

MATTISON'S BALANCED INSOLE SHOES

To the Editor—I received a pamphlet regarding Dr. Norman D. Mattison's balanced insole shoes manufactured by the Musbeck Shoe Company. Many things are claimed for these shoes and the feet are blamed for many illnesses. This booklet was handed to me by a local shoe dealer who has asked the status of Dr. Norman D. Mattison. Please let me have any data you have.

JOSEPH L. BEATON, M.D., Appleton, Wis.

ANSWER—Mattison is listed in the American Medical Directory as Mattison Norman D. (H) b76 N.Y. 9,06 107—(118 Union St., Montclair, N.J. 114) office 33 W. 42d St. New York.

As is so commonly the practice in making these pamphlets, unusual unreasonable and ridiculous claims are made. The chart showing a human skeleton is headed 'conditions related to faulty foot posture relieved by correct foot balance.' Many of the conditions mentioned may be related to faulty foot posture in certain cases, but they are not necessarily relieved by correct foot balance.

For example, to say that stiff neck, headache, congestion, strain, localized pain and neuritis of the head and neck can be relieved by correct foot balance is ridiculous.

Such terms as nervousness, compaction of the spine and neurasthenia are vague and indefinite, and should not be used in this connection.

The booklet contains the terms 'flat feet,' 'pronation,' 'muscle imbalance,' 'fallen arches' and 'weak ankles' as though they might not all be the same condition. The term 'defective gait' is indefinite.

It would be a blessing if a simple apparatus like a balanced insole shoe could correct the list of conditions mentioned. Of course to the intelligent person this is ridiculous.

Perhaps Mattison is 'one of the most famous foot specialists in America' but five members of the American Orthopedic Association who were consulted had never heard his name.

INTRAVENOUS MEDICATION FOR HYPERTENSION

To the Editor—I would appreciate information regarding intravenous medication for arterial hypertension due to arteriosclerosis in a patient about 60 years of age. Please omit name.

M.D., Pennsylvania

ANSWER—It is doubtful whether intravenous medication is justifiable for hypertensive arterial disease per se. Iodides injected intravenously cause a transient fall in the arterial tension, but this fall is not sufficiently prolonged to warrant clinical use. As iodides are readily absorbed from the alimentary canal, intravenous administration is clearly unjustified. In acute emergencies or vascular crises with sudden severe elevation of the arterial tension (as occurs in eclamptic and pre-eclamptic intoxication), magnesium sulphate administered either intravenously or intramuscularly may be of value. Thus introduced, magnesium sulphate is not cathartic but acts as a cerebral depressant and antispasmodic. Apparently the hypertonic 10 per cent magnesium sulphate causes cerebral dehydration or at least tends to diminish the cerebral edema that is a part of the eclamptic state. The dose for intravenous or intramuscular injection is from 4 to 10 cc. of a 10 per cent solution. The reduction of arterial tension persists for several hours and remarkable control over the convulsions has been reported. In acute glomerular nephritis with arterial hypertension, magnesium sulphate reduces the neuromuscular irritability and also diminishes the hyperpnea. Thus, in acute intoxications in which arterial hypertension is secondary to the intoxication and central nervous system irritation, magnesium sulphate may be of great value, but in the management of hypertensive arterial disease it has no place, especially in elderly patients. Its administration is not without risk, even in younger persons and acute myocardial injury is to be feared.

Relatively massive doses of calcium chloride in instances of severe renal injury with renal decompensation create diuresis and some reduction of the arterial tension. Except in instances of edema or severe renal failure, the intravenous injection of calcium chloride is not justified. Hypodermic injection of various tissue extracts for arterial depression has some highly enthusiastic advocates. A number of hepatic extracts have received extensive clinical trial, but the reduction of the arterial tension is too transient to be of lasting benefit. Hypertensive patients feel too well to continue hypodermic medication two or three times a week for months and any therapy of hypertensive disease must be long continued to yield satisfactory therapeutic results. Extracts from voluntary muscles and from the brain, kidneys, spleen and heart have all been studied; they all act quite similarly and produce a transitory decrease in the arterial tension and coronary dilatation. They are administered hypodermically, not intravenously. It is probable that the

effects of these various tissue extracts may be attributed to adenosin and not to so-called specific circulatory hormones. The experimental administration of adenosin phosphate results in circulatory changes almost indistinguishable from those induced by the various tissue extracts.

In the instance of a patient 60 years of age with hypertensive disease and arteriolar sclerosis, no intravenous medication is indicated or justified for the hypertensive disease per se. Should coincident difficulties arise such as cardiac decompensation, some intravenous medication might become indicated but not otherwise.

USE OF THYROID

To the Editor—A woman aged 63 has all the signs and symptoms of a lack of thyroid secretion. This is borne out by a basal metabolic reading which gives her rate as -22. I put her to bed about four weeks ago after she had been on 1 grain (0.065 Gm.) of thyroid for one week, and 2 grains (0.13 Gm.) for a week because she complained of weakness, anorexia and nervousness. At this time her pulse rate was 50, the same as it had been, and she appeared sluggish. At this time thyroid therapy was discontinued because she gave a history of the same effect several years previously when she was treated for the condition in another town. After three or four days at rest her appetite reappeared and thyroid 2 grains was again given with the same result as before, even though the patient remained in bed. Again when the thyroid substance was withdrawn the patient's appetite returned. I would appreciate any suggestions you may offer as to how I can administer thyroid medication with out these disagreeable symptoms. The patient feels better when she is taking the tablets except for the weakness produced by the inability to eat.

M.D., North Carolina

ANSWER—This story is rather puzzling and several points should be cleared up. Was the dosage of thyroid 1 grain a day or actually only "1 grain for one week"? If the latter then certainly she did not receive enough thyroid to have a physiologic effect. Furthermore, one wonders whether the pulse rate of 50 was connected in any way with disease of the heart, and whether the heart condition has been studied. It is most unusual for thyroid to decrease the appetite.

Two suggestions for treatment are offered. First that the thyroid be given to the patient without her knowledge of what medication she is receiving and if this is not successful, thyroxine might be used intravenously. With a basal metabolic rate of -23 there is little danger from the intravenous use of thyroxine. It is generally considered that 1 mg. will raise the basal metabolic rate approximately 2 per cent and that the maximum result occurs about ten days after the injection.

INFRACTION OF THE METATARSAL HEAD

To the Editor—Will you kindly tell me what Freiberg's infraction of the second metatarsal head is? I have not been able to find anything concerning it in textbooks on surgery. I am interested to know something of the pathology and symptomatology of this condition. Please omit name.

M.D., Wisconsin

ANSWER—Freiberg's infraction of the metatarsal head was first described by Freiberg of Cincinnati in 1913 in a paper read before the Southern Surgical and Gynecological Association. He saw his first case in 1903 but the paper reporting six cases did not appear until August 1914.

Kohler of Wiesbaden, Germany, described the condition in 1915 and reported five cases in 1920. The number of cases reported up to 1923 was sixty-three. Two cases were reported in an article by Philip Lewin in THE JOURNAL, July 21, 1923, page 189, bringing the total up to sixty-five.

The etiology of the condition is unknown. It is considered analogous to Legg-Calvé-Perthes disease occurring in the hip and to Osgood-Schlatter's upper tibial epiphysitis occurring at the knee. The important factors in the etiology are trauma, circulatory disturbances and infection. The gross pathologic changes consist of flattening of the metatarsal head with broadening of the neck and distal portion of the shaft and irregularity of the epiphyseal line, widening of the metatarsophalangeal joint space, and diminished cupping of the articular surface of the proximal phalanx with occasionally loose bodies or a line of incomplete fracture without displacement.

The symptomatology includes the uniform complaint of pain referred to the region of the affected metatarsal head, which is usually the second or third. Swelling is usually present. No marked increase of joint tension is demonstrable as a rule. There is a marked sharply circumscribed sensitiveness to pressure over the metatarsal head and the metatarsophalangeal joint. Abnormal local temperature is unusual. There is definite limitation of motion with muscle spasm. Abscess formation has not occurred in the cases reported. To the roentgen ray must go the credit of recognizing this condition. The changes revealed are flattening of the metatarsal head, broadening of

the neck and distal portion of the shaft, irregularity of the epiphyseal line, widening of the metatarsophalangeal joint space, diminished cupping of the articular surface of the proximal phalanx, and an occasional line of incomplete fracture without displacement

TREATMENT OF RESISTANT ACNE

To the Editor—A man of my acquaintance has had acne for about fifteen years. He is yet under 30 years of age. He has had the vaccine therapy, the roentgen treatment, diets (mostly consisting of the leaving off of sweets and starches), examinations giving negative results, tonillectomy, appendectomy and various drugs including tin and yeast but he still has acne although it probably is getting better since it does not seem to be as severe as it was ten years ago. Even now though it has exacerbations and there are a few eruptions all the time. It has been severe on the face, neck, back and chest and now it is on the arms and is coming down on the forearms. The eruptions are not only small pimples but mostly larger boils. The exacerbations come with or without treatment. Treatment does not seem to have any effect. I might add that the Wassermann reaction on two occasions has been negative. There is a family history on the father's side of some acne but nothing like the present severe form. Do you have any recommendations as to any thing that might give relief? I realize that this is a problem that has been unsuccessfully combated for many years. Please omit name.

M D Georgia

ANSWER—One should make sure that there is no focus of infection and that the gastro-intestinal tract is functioning normally. If secondary anemia is present it should be corrected. Daily habits and personal hygiene (including sex habits) should be of a kind that is conducive to health. If there is much dandruff of the scalp the scalp and hair should be washed twice weekly with green soap and a suitable lotion should be applied daily.

The skin of all the affected areas should be kept very dry and even chapped by using the following treatment. The skin of these parts should be washed every night with ordinary green soap. Then the subjoined lotion should be well shaken and sopped on all the areas where lesions tend to appear.

Betanaphthol	0.25	Cm.
Solution of sulphurated lime filtered	15	cc.
Zinc sulphate	15	Gm.
Sulphurated potassa	15	Gm.
Rose water sufficient to make	120	cc.

The zinc sulphate and the sulphurated potassa are dissolved separately in half the rose water. These two solutions are then combined. Finally the solution of sulphurated lime and the betanaphthol are added. It may help to apply ultraviolet radiation in suberythema doses to the entire body daily, and in erythema doses to the affected areas twice weekly.

SPASTIC DYSMENORRHEA

To the Editor—A woman aged 24 has had dysmenorrhea since she was 14 years of age. During the first three days of each menstruation she has severe pain in the lower part of the abdomen with nausea and vomiting. The most prominent symptom of her condition is vomiting. I have seen cases of dysmenorrhea but the vomiting in this case is something I have never heard of. She vomits constantly for three days, becomes dehydrated and is on the verge of acidosis. About a year ago on recommendation of another physician she had an application of a small dose of radium. She was told that her menstruation would cease for about a year to sixteen months. Following the application of radium her menses ceased and she was free of all the symptoms for seven months. In the last few months however the old symptoms have reappeared. With each apparent menstrual period she has severe pain and constant vomiting for three days but there is no menstrual bleeding. Also instead of having this once a month she has it now twice a month. Her physical examination is negative except that during menstruation there is an enlargement of the thyroid. The basal metabolism is normal. Will you kindly suggest what can be done for her? Especially the vomiting. What about endocrine therapy? Why have the symptoms reappeared without menstrual bleeding? Please omit name.

M D

ANSWER—The patient apparently suffers from primary spastic dysmenorrhea, a condition caused by one or a combination of the following factors: (1) hypoplasia (subpubescence) of the uterus, with a preponderance of fibrous over muscular elements, (2) cramplike uterine contractions due to an excess of estrin in the blood, (3) psychogenic factors, and (4) constitutional causes. In the light of most recent experimental work (Novak and Reynolds) the second cause given appears most plausible. One cannot, however, exclude the influence of psychogenic factors in this case, particularly in reference to the nausea and vomiting.

The fact that the subjective symptoms returned periodically without the appearance of bleeding may be explained by a resumption of ovarian activity after a seven months complete inhibition due to the action of radium. The follicular apparatus again responds to the stimulation of prolactin A from the hypophysis, and the estrin thus produced exhibits its effect on the uterine musculature. The endometrium, however, has not

regenerated sufficiently to respond to the action of the hormone. The nausea and vomiting, while possibly explained as reflex symptoms of pelvic origin, are more likely explained on a neurotic basis.

Therapy should be directed along general lines with special emphasis on advice concerning sex hygiene, special exercises, and psychotherapy (advisedly outlined by a psychiatrist). Endocrine therapy in dysmenorrhea is still in the experimental stage. Small doses of thyroid extract may be helpful.

STERILITY AND NECROSPERMIA

To the Editor—I have a patient who has been married for more than ten years and is sterile. The wife of the patient had an endocervicitis and gives a history of a vaginal discharge which cleared up by local treatment and cauterization. Her tubes have been proved to be normal by roentgen examination after injection of iodized oil. Her Wassermann reaction is negative, her general health good. Her tonsils are questionable or apparently infected. The husband's history is of some urethral discharge in Sweden some years ago before marriage diagnosed by the physician at that time as not gonorrheal for which he was not treated and he has never noticed any discharge since. He is markedly obese weighing over 200 pounds or 90 Kg (overweight for his height). The Wassermann reaction is negative. His general health is good. After massage of the prostate which is slightly enlarged, urethral smears showed many pus cells but no gonococci. Examination of the semen within the proper time of coitus showed many in the field but they were without motility or dead. Under local treatment of massaging the prostate and vaccines the urine is clearing up. There is no stricture of the urethra. Have you anything else to suggest in the case for dead spermatozoa? If the spermatozoa come back to life and without results would you suggest a dilation and curettage?

WILLIAM FRANKMAN M D Boston

ANSWER—Sterility in this couple is due to the male factor, necrospemia being the direct cause of the failure to conceive. In addition to the local genital disturbance the husband should be treated for obesity, which probably is due to metabolic disturbances. There is no indication to treat the female partner and no reason for dilation and curettage. When the husband presents satisfactory spermatozoa, the postcoital and tubal patency tests may be repeated.

USE OF THYROID IN ICHTHYOSIS

To the Editor—I have under my care a white man aged 26 who is decidedly underweight (108 pounds or 49 Kg) his height is 5 feet 8 inches (173 cm). He also has a very rough scaly skin especially on the back, arms and legs. In spite of all efforts to gain weight such as rest and tonics he constantly maintains the foregoing weight. His basal metabolism is -12 the blood sugar is 85 mg, the heart and lungs are normal, the Wassermann and Kahn reactions are negative. I might mention that his father suffers from such skin trouble to a lesser degree as does also one sister and one brother. There is no scantiness of hair except on the legs and thighs where the skin is so rough it actually imparts the feeling of sandpaper. My question is this: Would not thyroid extract tend to cause a further decrease in weight or would insulin while causing an increase in weight, also clear up this skin condition? Kindly omit name.

M D Ohio.

ANSWER—The skin condition is evidently an ichthyosis. Although the dosage of thyroid extract necessary to improve the skin should not cause any loss of weight, it might be wise in this case to give insulin first in an effort to increase weight. Five units half an hour before each meal is the best stimulant for the appetite. The increase of weight might have some slight beneficial effect on the skin, increasing the production of sebum and the thyroid extract will not interfere with the effect of the insulin.

TIME INTERVAL AND PROOF OF DEATH FROM POISONING

To the Editor—What is the longest time a body has been buried and then taken up to ascertain the cause of death? Is it possible to secure definite pathologic proof of poison having been taken after the body has been buried for some time?

MILDRED E. JEFFREY Dayton Ohio.

Executive Secretary Montgomery County Medical Society

ANSWER—Bodies have been exhumed and examined years and years after burial. No definite time limit may be fixed for the longest interval between burial and examination. In the case of mummies, thousands of years may have elapsed. In the case of certain historical persons, examinations of the bodies have been made hundreds of years after death. Definite evidences of corrosive and coagulating poisoning may be obtained after the body has been buried for some time, provided of course, that it is fairly well preserved. In the case of bodies well embalmed with formaldehyde solution, such evidence may be obtainable months and perhaps years after burial.

DUODENAL DILATATION

To the Editor—A white woman aged 26 has a marked duodenal dilatation the result of partial obstruction at the duodenojejunal angle. Different methods of raising the lower abdomen have produced no alleviation of weight loss vomiting and epigastric discomfort after meals. This condition has been present for four years and although her weight has dropped from 115 to 75 pounds (from 52 to 34 Kg.) her vitality is fairly good. What further medical treatment would you advise? What has surgery to offer? Please omit name.

M D Pennsylvania.

ANSWER—There is usually an alkalosis in cases of this type. If hydrochloric acid has not been tried, it might be beneficial if used in full doses after each meal. Because of the length of time the trouble has lasted and the statement that raising the lower abdomen has not alleviated the condition most likely it will be necessary to have surgical aid. An anastomosis of the duodenum to the jejunum proximal and distal to the obstruction usually brings excellent results.

EFFECT OF AMPUTATION ON BLOOD PRESSURE

To the Editor—Would the amputation of the lower extremities one at the hip joint the other below the knee have any end results on the blood pressure?

S C Broadstreet M D Mount Pleasant Texas

ANSWER—Such amputation as mentioned would not have any end results on the blood pressure so far as loss of blood is concerned particularly if the tourniquets are applied appropriately so as to render the limb quite bloodless prior to the operation. Even so such loss of blood (retained in the limbs) would be compensated for by an increase in the general vasoconstrictor tone. Certainly the surgical shock likely to attend a double amputation of this type with the usual and profound drop in the general arterial blood pressure is of greater practical moment than the actual loss of blood (hemorrhagic shock). On complete recovery from the operation, the blood pressure will assume its preoperative level.

KELOID

To the Editor—A patient aged 25 was bitten on the face by a dog eighteen years ago. The wound healed promptly and gave no trouble until recently when a nodule was noticed under the scar. As the scar was very irregular the scar and nodule were removed a nice straight scar being left in the natural crease. The scar now appears thickened through its entire length and is slightly prominent. This in my judgment is a keloid and if you agree with my diagnosis which do you advise using x-rays or thiosinamine? If you advise the latter kindly give method and solution formula.

M D

ANSWER—The condition as described is one of hypertrophic or keloidal scar. Being of recent development, it should respond rather promptly and satisfactorily to radiation therapy either x-rays or radium may be used. Thiosinamine is a drug used extensively in India where radiotherapy is generally inaccessible. It is destructive in its action and may leave unsightly scars.

TREATMENT OF RANULA

To the Editor—A patient has a stenosis in the duct of his right submaxillary gland so that there is a ranula at the base of the tongue about 1½ inches from the frenum. Although I have several leading works on surgery I do not find in them any good or detailed statements of methods of treatment. Please omit name.

M D New York

ANSWER—Methods of treatment are described by

Thompson J E. Relationship Between Ranula and Branchiogenic Cysts. *Ann Surg* 72: 164 (Aug.) 1920

Blair V P. Ranula. *Ann Surg* 77: 681 (June) 1923

Gilmer T L. Lectures on Oral Surgery. L. S. Matthews 1903

INJURY TO LIP DURING EXTRACTION OF TOOTH

To the Editor—On page 1362 THE JOURNAL, April 29 a correspondent asks about an injury to the lip of a child during tooth extraction under local anesthesia. I have seen a number of these cases and believe that they are due to the anesthetic solution rather than to a bruise. Sterling V Mead in Diseases of the Mouth first edition page 327 discusses the condition and designates it neurotrophic ulcer. His description follows:

Ulcers appear on the lower lip near the angle after extraction of the teeth under local anesthesia. The ulcers appear the day following mandibular injection and vary in size from that of a dime to that of a quarter. They are not painful and have the appearance of a circumscribed piece of pearly white tissue superimposed on the epithelial tissue. They are probably due to irritation of the nerve in a susceptible person or to a solution which is too hot. It seems likely that the condition referred to probably was of this type.

Book Notices

Chronic Arthritis and Fibrositis. Diagnosis and Treatment. By Bernard Langdon Wyatt MD FACP Director The Wyatt Clinic Tucson Arizona. Cloth. Price \$3.50. Pp 201 with 17 illustrations. Baltimore: William Wood & Company 1933.

Although the interest of the medical profession in chronic arthritis is growing it is still far from being commensurate with its medical, social and economic significance. The author of this volume has rightly emphasized that the main task of caring for patients suffering from this disease belongs to the general practitioner, an obligation which has been largely side-stepped in favor of the specialists, the spa physicians and the cultists. The book is intended as a handbook to provide the practitioner with a concise review of current knowledge on cause and treatment, it contains numerous practical suggestions and pertinent dicta. Although in reality it is a second edition of the author's book "Chronic Arthritis and Rheumatoid Affections" it has been so thoroughly revised and its general tone so altered and improved as to lay fair claim to its being a new book with the right to a new title. The causes, diagnoses and treatments of proliferative (atrophic) and degenerative (hypertrophic) arthritis of fibrositis (muscular rheumatism) and of gout are considered. The interesting statistics of Dublin on the mortality and morbidity from these diseases are reprinted from the former edition. The general principles of physical therapy and suggestions on prevention of deformity are discussed as are the uses of diets, drugs, vaccines and climato-therapy. The format is greatly improved over that of the first book. The book is open to the criticism that a considerable amount of it is from other publications. Roentgenograms, photographs and large portions of text are borrowed from the works of others, to whom credit, however, is generally given. The author's summary of his own experiences and of the results of treatment of his patients are so briefly condensed in the final chapter of only nine pages as to give the impression of an apologia. Perhaps there is too much deference to the experiences and opinions of others, thereby weakening the author's claim to personal authority. Regardless of this and of a few minor discrepancies the work is a practical introduction to the studies of these diseases. Although the author has not been sufficiently critical in some respects the book is free of personal fads and it presents in the main an honest summary of current opinion.

Anleitung zur frühzeitigen Erkennung der Krebskrankheit im Auftrage des Landesausschusses zur Erforschung und Bekämpfung der Krebskrankheit in Sachsen. Bearbeitet von Best, Fromme, Payr, Rostok, Seip, Schmorl, Tonndorf und Warnekroe. Boards. Price 3 marks. Pp 134. Leipzig: S. Hirzel 1932.

This volume was written on the request of the committee for investigation and combat of cancer in the state of Saxony, Germany, for the purpose of being a reliable guide to the general practitioner in one of his most responsible tasks, the early diagnosis of cancer. It must be admitted that the fate of cancer patients lies almost entirely in the hand of the general practitioner, since it is he who first sees the patient and on whom the responsibility rests as to the early diagnosis. Early diagnosis, however, is the *conditio sine qua non* in the successful treatment of cancer. In an excellent manner and without unnecessary theoretical ballast the presence of malignant disease in the various organs is discussed by the various authors. Much stress is laid on the clinical recognition of first signs and symptoms and on the differential diagnosis of cancer, while progress of disease and treatment is discussed somewhat less in detail. Cooperation with the specialist is urged whenever suspicion of malignant disease is aroused and no definite diagnosis can be reached. Although the book is written chiefly for the general practitioner, the specialist also might find some valuable hints and notes as to the early appearance of cancer in the various parts of the body.

Specific Changes in the Blood Serum. A Contribution to the Serological Diagnosis of Cancer and Tuberculosis. By S. G. T. Bendien. Serological Laboratory Zeist Holland. Translated by A. Piney MD Director of the Pathological Department The Cancer Hospital London. Cloth. Price \$3.00. Pp 95 with 64 illustrations. St. Louis: C. V. Mosby Company 1932.

This monograph contains the author's work of a flocculation test according to which it is possible to obtain a specific reaction by mixing serums with different concentrations of mixtures of acetic acid and sodium vanadate. While serums of normal persons flocculate at a certain concentration (tube 6), flocculation always occurs in lower concentration (below tube 6) in pathologic conditions such as carcinoma chiefly, but also tuberculosis, eclampsia and pregnancy. The author, however, admits some exceptions of that behavior and states that the reaction is not specific in definite diseases. Many statements are made with restrictions, and further investigations are announced. Since the reaction frequently was found to be positive in serums of carcinoma, tuberculosis, pregnancy and syphilis, known to be 'labile' serums it seems more than likely that Dr Bendien's reaction must be encountered among the nonspecific lability reactions. In 'labile' serums in which a disturbance in the colloidal structure of the plasma protein and in the globulin-albumin ratio is known to occur, flocculation or precipitation is likely to be produced by various substances. This is made all the more probable as Dr Bendien states that flocculation in the lower concentration was always parallel with increase of globulin, and vice versa. The translator says: Time alone can show the practical value of Dr Bendien's observations but there can be no doubt that this book presents a number of new facts.

La technique de la curiethérapie. Par Simone Laborde chef du service de curiethérapie à l'Institut du Cancer. Les actualités physiothérapiques. Publiées sous la direction du Dr Dubem. III. Curiothérapie. Paper. Price 20 francs. Pp 121 with 12 illustrations. Paris: Gauthier Villars & Cie 1933.

The introductory chapter on radiobiology of tumors discusses various theories concerning the biologic aspects of radiation. The theories of direct and indirect action of radiation, radiosensitivity and radioimmunity and the biologic effects of rays of varying quality are presented in some detail. Special attention is devoted to the time factor in radiation therapy. The author cites certain objections to Regaud's theory concerning the effect of the time factor on the radiosensitivity of neoplastic cells. The second chapter discusses the differences in biologic effects of beta and gamma rays and the effects of filtration. The principles and technique of telecurietherapy are briefly discussed and the construction of different apparatus used in various clinics is described. The relative advantages and disadvantages of radium element and radon are accurately presented and the conclusion drawn that the use of radon is best restricted to large centers and that radium element is economical and convenient in smaller centers. The latter method,

possesses some advantages over the former. The technic of surface irradiation and radium puncture is discussed and brief reference made to various forms of applicators. The author presents the points of view of the two opposing schools one based on massive irradiation, the other on division of the irradiation over a period of several weeks. The value of prolonging the irradiation in cancer of the skin and in cancer of the uterus is in the author's opinion not fully established, whereas she concedes the advantage of protracting the irradiation in the treatment of cancer of the mouth, larynx and pharynx. The use of massive irradiation in very short intervals is correctly condemned. The last chapter concerns itself with dosimetry and a description of methods of measurement. This small volume is a distinctly limited but accurate presentation of the principles and technic of radium therapy.

Neurology in Podiatry. By Joshua H. Leiner, M.D., Associate Attending Neurologist, Jewish Memorial Hospital, New York City. Edited by Maurice J. Lewi, M.D., Professor of Medical Jurisprudence, Albany Law School. Cloth. Price \$2.50. Pp. 120 with 9 illustrations. New York: Harriman Printing Company, Inc. 1932.

The purpose of the author is to present a neurologic textbook touching on the problems related to podiatry. He offers the practicing podiatrist a book that will help him recognize and aid in the elucidation of neurologic diseases and foot deviations that occur almost daily in his practice. He warns against the conception that foot conditions are isolated from the patient as a whole. The author believes that this booklet supplies a gap, namely, the essentials of neurology as they apply to the needs of the student of podiatry and the practitioner of that specialty. The author states that, in his opinion, infantile paralysis is as prevalent as measles but appears often simply as a mild cold with constitutional symptoms but without paralysis. This statement is open to severe criticism. This book should be of some value to students and practitioners of podiatry. It would seem that \$2.50 is a lot of money to pay for the material.

Le genou. Anatomie chirurgicale et radiographique chirurgicale opératoire. Par Antoine Basset, professeur agrégé à la Faculté de Paris. Paper. Price 45 francs. Pp. 180 with 120 illustrations. Paris: Masson & Cie. 1932.

This brief and clearly written review of the knee in its surgical and anatomic aspects fills a want for the average surgeon covering particularly the surface and immediate underlying anatomy and technical descriptions of the avenues of approach to the joint. Too much attention and space however are given to a description of the incision into the knee joint to the detriment of any indications for its use. There is likewise a great deficiency in describing the pathology of various conditions involving the knee joint which may require operation or the indications for operation. The illustrations are enlightening and contain some new points not found in other works on this subject. The literature is fairly well covered as applied to some of the operative procedures advised. A few American authors are credited with their work. The book offers a rather ready reference for technical information on surgery of the knee joint but has little value beyond that.

The Pelvis in Obstetrics. A Practical Manual of Pelvimetry and Cephalometry including Chapters on Roentgenological Measurement. By Julius Jarcho, M.D., F.A.C.S., Consulting Gynecologist, Haslinga Hillsido Hospital, New York. Cloth. Price \$6. Pp. 365 with 140 illustrations. New York: Paul B. Hoeber, Inc. 1933.

The author begins his preface with the remark that there is no work in the English language which covers the subject of the proper measurement of the pelvis and fetal head in adequate detail. In this he errs, because the textbooks by De Lee and by Williams discuss this subject adequately. He is correct, however, in his lamentation that unfortunately the trend of recent years has been toward the neglect of pelvic measurements with reliance on a dangerous test of labor. The book concerns itself almost exclusively with pelvimetry and cephalometry not only by means of the hands and pelvimeters but also by the use of special roentgen procedures. The author has made intensive studies of roentgen pelvimetry and cephalometry and is therefore well qualified to write on this subject. In the discussion of normal pelvis he takes up racial and national differences and their practical importance in obstetrics. The book is well printed, the illustrations are beautifully drawn, and the language

is simple and clear. There is an extensive bibliography and a commendably detailed index. Because of its limited field and because the essentials are included in all modern textbooks on obstetrics and have been written up in various medical journals in recent years there will probably be a limited demand for this book. However, it should be in the library of every obstetrician as a valuable work of reference.

Atlas der Erkrankungen der oberen Luftwege mit besonderer Berücksichtigung des Epipharynx. Von Dr. Siegfried Gräff, leitender Oberarzt am pathologischen Institut des Allgemeinen Krankenhauses Barmbeck in Hamburg. Lieferung 1. Paper. Price 17 marks. Pp. 33 with 36 illustrations. Leipzig: Curt Kabitzsch. 1933.

This is the first third of an atlas devoted to the diseases of the upper air passages, with particular reference to the epipharynx. The author has by special postmortem technic evolved a method of removing, in one mass, sufficient of these structures composing the upper air and food passages to illustrate with great effectiveness the diseases affecting these parts. The atlas consists of reproductions of photographs, many of them are colored and all of them are excellent. The diseases treated in this part, among a number, include hyperplasia and fresh tuberculosis of Waldeyer's ring, diphtheria of the pharynx with extension into the nasal cavities as well as the larynx and trachea, stenosis of the epipharynx, and primary carcinoma of the pharyngeal tonsils. In each instance there is a short case history, a summary of the postmortem observations, and adequate descriptions of the illustrations (there are numbers of them from each case). The author is to be congratulated on his praiseworthy effort.

Physical Therapy in Infantile Paralysis. By Arthur T. Legg, M.D., Assistant Professor of Orthopedic Surgery, Harvard and Janet B. Merrill, Director of Physical Therapeutics, Children's Hospital and Harvard Infantile Paralysis Commission, Boston. Reprinted from *Principles and Practice of Physical Therapy*, Edited by Doctors Harry E. Mock, Ralph Pemberton and John S. Coulter. Cloth. Price \$1.50. Pp. 88 with 46 illustrations. Hagerstown, Maryland: W. F. Prior Company, Inc. 1932.

This monograph is a reprint of a chapter from *The Principles and Practice of Physical Therapy* by Drs. Mock, Pemberton and Coulter. This section was written by two authorities on the subject and reflects the best work being done. The authors divide the subject, the course and treatment of anterior poliomyelitis, into four stages. There is an instructive chart showing the symptoms and signs in the febrile stage of the disease. During the last few years there has been definite progress in the treatment of infantile paralysis. These advances fall to a certain degree into the field of physical therapy. The objects of treatment during the second stage are the prevention of early deformities and the relief from sensitiveness. The authors recommend that active physical therapy should be started when the sensitive stage is over, that is at the beginning of the third or convalescent stage. Before any intelligent physical therapy or reeducation of the affected muscles can be started, a complete muscle examination must be made to show the extent of paralysis and the comparative strength of the different muscle groups. The treatment recommended during the third stage should lay emphasis on the prevention of fatigue and of deformity. This is the time, above all others, to concentrate on measures to reeducate the muscles and to develop strength wherever response can be obtained. They recommend the application of some form of external heat to be included in the first part of the physical therapy in any case of infantile paralysis in which the muscles are extensively involved. The physiologic effects of massage are similar to those of heat in that both increase the blood supply and keep up metabolism. The section on muscle training was arranged by Miss Janet B. Merrill.

The general purposes in muscle training in poliomyelitis are to maintain and improve the circulation and nutrition, to maintain muscle tone and prevent degeneration and atrophy of muscle fibers from disuse or from joint adhesions in cases in which the motor nerve supply is partially or temporarily interrupted, to keep up tone in muscles whose nerve supply has been unimpaired during the period of recumbency or disuse, to coordinate the remaining nerve centers when partial destruction of the centers controlling a part has occurred—reeducation by habit—while at the same time developing the fibers of the muscles that are still functioning normally, thus increasing the

strength of the entire muscle, to develop coordination and control.

The general rules for muscle training are to avoid over-fatigue of a muscle by overtreatment by performing a movement rapidly or too many times, make each movement a voluntary active one performed by the patient in response to a stimulus see that the full arc of motion is obtained each time localize the exercise by fixing the adjoining parts of the body so that they will not take part in the movement, give resistance to develop strength wherever possible.

Radiant heat with massage is desirable before the treatment is given to start the circulation and make the muscle give a better response. Ordinarily treatment is given once a day, six days a week. If the splint or apparatus is removed, care should be taken not to allow the part to hang, and no stretch or strain should be allowed on the muscles that are being kept shortened in the splint. The part that is being exercised should always be uncovered. If possible, one should be alone with the patient in order to secure his entire concentration.

In conclusion, the authors offer a concise statement of what can be expected from physical therapy. The illustrations are excellent, particularly some instructive and easily understood pictures of braces on and off the patients, and pictures of a walking apparatus and a hydrotherapy pool. This chapter should be of great value to every physical therapist and orthopedic surgeon.

Studies on Alimentary Lipemia in Man. By N. I. Nissen. Paper Pp 176 with illustrations. Copenhagen. Levin & Munksgaard 1933.

This well printed monograph is essentially the record of an attempt to establish a normal tolerance curve for fat analogous to the dextrose tolerance test. The section containing the detailed description of the author's work and results is preceded by a rather elementary chapter on the chemistry of fat, a second chapter containing an excellent analysis of the known methods for extraction and estimation of the various fat fractions of the blood, and a third chapter which summarizes the scientific literature on the triglyceride and lipid content of the blood in fasting normal individuals. Using the Bing-Heckscher method for estimation (on an ether extract of 0.1 cc of blood) and a test meal containing about 1 Gm of fat, in the form of cream, per kilogram of body weight the author establishes a normal curve which varies within rather wide limits. The effects of consecutive tests and the influence of simultaneous carbohydrate ingestion, as well as the deviations from normal in several pathologic states are reported. This volume which contains an excellent bibliography, will make a valuable addition to the library of those especially interested in fat metabolism, but it is hardly of clinical significance. The translation from the Danish is generally intelligible but often foreign in its idiom.

An Index of Prognosis and End Results of Treatment. By Various Writers. Edited by A. Rendle Short. M.D. B.S. B.Sc. Hon Surgeon Bristol Royal Infirmary. Fourth edition. Cloth. Price \$12. Pp 599. Baltimore. William Wood & Company 1932.

An Index of Treatment. By Various Writers. Edited by Robert Hutchison. M.D. F.R.C.P. Physician to the London Hospital. Tenth edition. Cloth. Price \$12. Pp 1027 with 93 illustrations. Baltimore. William Wood & Company 1931.

These two volumes are part of a series developed by William Wood & Company and now issued over a period of some twenty years. Nine years has elapsed between the last two editions of the Index of Prognosis. This book, therefore, has been extensively revised, particularly as concerns the anemias, diabetes, cancer and intestinal obstruction, subjects in which prognosis has been greatly changed as a result of development of new methods of treatment. Attention is called to a new article on the various forms of mental disease treated according to modern classifications. The book is exceedingly useful not only as a guide to the physician in advising his patients in things they want to know, namely 'How long shall I be sick?' and 'Shall I get well?' but also as a guide to the literature of the subject and to new forms of treatment that have modified the course and prognosis of disease.

The Index of Treatment was previously issued in 1925. Six years has elapsed, therefore, to the time of production of the present volume, which is dated 1931. The book is a symposium volume in which more than a hundred physicians have cooperated, all of them, however, British. It is therefore an adequate

guide to British methods but for American physicians has the disadvantage of the use of the British pharmacopoeia and the mention of a considerable number of preparations not available in this country. One reads with amusement that redness of the nose is an indication of dyspepsia and can be treated by a stomach mixture containing bismuth carbonate and bicarbonate of soda. One fails to find any reference to surgical methods in the treatment of Raynaud's disease. The article on scurvy suggests fresh fruits and vegetables, but the word "vitamin" does not occur in it. The book contains a great deal of exceedingly useful material, particularly if the suggestions are read with judgment.

Chronic Rheumatism and the Pre Rheumatic State. By J. D. Hindley Smith. M.A. M.R.C.S. L.R.C.P. Cloth. Price 5/6. Pp 154. London. H. K. Lewis & Company Ltd. 1932.

The author presents a plea for further research and inquiry into the problem of the prevention of chronic rheumatism. He summarizes the results of his clinical work during the past five years. He believes three fourths of the victims of chronic rheumatism could have been saved from their suffering if the condition had been recognized early enough. He believes not only that the disease is becoming more common but that its worst features are to be found at an earlier age with each successive generation. 'Our parents complained of it at 60 and we ourselves are aware of it soon after 40 whereas it is now common in the rising generation during the 20's.' He estimates that one sixth of the working population of the United Kingdom is unable to work on account of chronic rheumatism. He summarizes the infective, metabolic and endocrine theories of etiology. In discussing vaccine therapy he says that if as is definitely proved vaccines are of great value in certain cases their failure in other cases cannot be due to a fault in principle but to some error resulting from ignorance or lack of experience either in technique or in the selection of the cases in which a vaccine should be employed. The author asks the following questions: 1. Has the streptococcus developed a tendency to alter in character and virulence during the past fifty years? 2. Has the streptococcus remained the same, but the reaction of the human race altered in relation to its activities during that time? 3. Have the various acute manifestations of streptococcal activity which were generally recognized in the past tended to produce in humanity a gradually increasing power of resistance to acute streptococcal disease, so that now, instead of causing an acute febrile disturbance which either killed or cured its victim, there results a long drawn out chronic warfare in which the victim suffers from a slow poisoning of the system? 4. Is humanity as a whole losing something of the quality of resistance against bacterial infection owing to the artificial conditions of civilization, which act by sterilization and disinfection as a protective barrier between ourselves and the bacterial world? 5. Are we becoming more 'allergic', that is, owing perhaps to more specialized development of the nervous system, more easily sensitized to foreign chemical substances, particularly proteins, which enter the blood from time to time so that these substances more easily become toxic to us, and produce signs of disease. The author has provided material of a sufficiently suggestive nature to provoke interest along similar lines. This little book is well worth reading.

The Organs of Internal Secretion. Their Diseases and Therapeutic Application. With a Chapter on Obesity and its Treatment. By Ivo Gellike Cobb. M.D. M.R.C.S. Fourth edition. Cloth. Price \$3.50. Pp 303. Baltimore. William Wood & Company, 1933.

Here are an introduction, sixteen chapters, bibliography and index. The first edition published in 1916 was founded on articles the author had written for the *Medical Press and Circular*. There is rather more history than should be included in a work of this size. Too much of the book is devoted to theory particularly theories that now have little standing and but few facts to support them. The author has failed moreover, to include some of the late work that must have been available while this edition was in course of preparation. The author questions whether vitamin D acts by simple stimulation of the parathyroids and feels that the evidence now is not sufficient to support that theory. He quotes Rendle Short to the effect that thyroid extract is quite as effectual as potassium iodide in tertiary syphilitic ulcers. He presents a beautiful picture of exophthalmic goiter and questions whether the thyroid

may not be more sinned against than sinning. He clings to the old classification designed by Plummer. "It is impossible to lay down any hard and fast rule to decide whether surgery should or should not be utilized in cases of Graves disease (as opposed to toxic adenomata)." The interesting suggestion is offered that patients suffering from thyroid deficiency who are unable to tolerate even small doses of thyroid are frequently helped by the addition of small doses of parathyroid. Dr. Cobb cautions about the use of thyroid extract and is of the opinion that the initial dose is usually too high. The action of the various hormones in the anterior lobe are enumerated but in discussing clinical cases he does not differentiate closely as to the lobe involved. There are some inconsistencies. For example, the text indicates that the author does not know about the isolation of the hormone from the suprarenal cortex, yet it is included under the list of preparations. In discussing endocrine glands in nervous disorders, the author limits himself largely to a discussion of the war neuroses. When it comes to dementia praecox he confines himself to theory, which is not plausible and is not supported by evidence available now. In the application of hormones, the author indulges in more empiricism than is warranted and fails to include much specific therapy that might have been mentioned. Obesity and its treatment are well handled. He is quite properly of the opinion that a relatively small part of obesity is due to simple overeating and is of the opinion that something has gone wrong with the patient's metabolism which prevents his handling an average amount of food without laying on an excess amount of fatty tissue. The book cannot be said to contribute much to our knowledge of the glands of internal secretion and to the diagnosis and treatment of their disorders.

Note di Immunoterapia in otorinolaringologia. Da Dott. P. C. Monti otoriatra dell'I. P. P. A. I. di Milano. Paper. Price 20 lire. Milan. Istituto Sferoterapico Milanese 1932.

This is a complete review in condensed form of the general theory underlying infection and immunity, with a rather comprehensive history of the development of the specialty of otolaryngology. Infections of the ear, nose, throat and larynx are briefly described, and the uses of the various types of biologic therapy, vaccine—antitoxins, bacteriophage and antiviruses—are clearly discussed. The author's advice as to the employment of these agents is generally conservative. Their employment is nowhere presented as a cure all but rather as a valuable adjunct to the surgical, constitutional and local treatment that may be indicated. In this respect this little manual is decidedly different from the usual publications emanating from manufacturing institutes of biologic products. Reference is occasionally made to proprietary antiseptics and other pharmaceutical products of unknown composition and not included in N. N. R. Otherwise the author has succeeded in his effort to present a scientific condensed summary of the biologic therapy of infectious processes of the ear, nose and throat.

A Textbook of Materia Medica for Nurses. By Edith P. Brodie. A. D. N. Fourth edition. Cloth. Price \$2.25. Pp. 324 with 16 illustrations. St. Louis. C. V. Mosby Company 1933.

This textbook seems to cover the subject of materia medica for nurses acceptably. In view of this one regrets to note three errors in each of the two prescriptions quoted on page 166, also that the word fluidextract which in the present pharmacopeia has been contracted into one word is written in two words as it was in the older pharmacopeias.

Chronic Enteric Carriers and Their Treatment. By C. H. Browning with H. L. Coulthard, R. Cruickshank, K. J. Guthrie and R. P. Smith. Medical Research Council Special Report Series No. 179. Paper. Price 1s. 6d. Pp. 80. London. His Majesty's Stationery Office 1933.

The authors review recent literature on the importance and incidence of typhoid and paratyphoid carriers, the method of identification of a carrier and the possible methods of treatment. They also include a study of their own on eight intestinal excretors and two urinary carriers. The practical significance of intermittence of excretion is fully recognized. Nonsurgical treatment of intestinal excretors is considered ineffective but when the gallbladder is the site of infection the application of surgical measures, cholecystectomy or, more rarely, cholecystostomy has yielded highly satisfactory results. The report is clear, concise and marked by good judgment.

Medicolegal

Proving Osteopathic Malpractice

(Williams v. Marini (11) 162 A 796)

The defendant, a licensed osteopath, called on the plaintiff for the first time on the morning of August 15. On the afternoon of the same day, using novocaine as a local anesthetic, he removed the nails of two of the plaintiff's toes which he said were already infected. He continued in attendance until August 22. On the following day a medical practitioner who had replaced the defendant osteopath found the toes gangrenous and that they had been so for at least three or four days. The case was diagnosed as dry gangrene and after waiting for the appearance of a line of demarcation the leg was amputated above the knee. The patient sued the defendant osteopath, charging negligence. From a judgment in favor of the patient, the osteopath appealed to the Supreme Court of Vermont.

The defendant testified that at the outset he tested the patient's circulation by palpation only. Osteopathic witnesses testified however that although that procedure was correct as far as it went in a case like the one under consideration it was not sufficient. The heart should have been tested, the blood pressure taken and an analysis of the urine made. One osteopath testified that when the discoloration extended up the foot it evidenced a serious condition, caused by faulty circulation, and probably indicated that the case should be turned over to a surgeon authorized to do major surgery. Another osteopath testified that the defendant's treatment was not up to the standard of good osteopathic practice, which required that the hot applications that the defendant applied to stimulate the circulation be supplemented by manipulative work. There was no error said the Supreme Court in refusing the defendant's motion for a directed verdict and submitting to the jury the question of the defendant's negligence. One who employs a physician is entitled to a reasonable and thorough examination before a remedy is applied. What such an examination involves depends somewhat on the patient's condition and the opportunities for examination open to the physician. The physician's conduct is to be judged not only by what he discovers by examination but by what he ought to discover, that is to say, by what the average practitioner of his particular school in that general locality would discover.

In making a motion for a directed verdict, in the trial court the defendant osteopath relied in part on an allegation of contributory negligence on the part of the patient. The court refused to grant the motion but instructed the jury that a sick man is not expected to exercise the same discretion and judgment as a well man. That instruction said the Supreme Court, was not error as applied to the present case. The evidence tended to show that the patient was suffering intense pain during the defendant's treatment and could not sleep during that time. The question of contributory negligence always turns on what a prudent man would do under the circumstances. It was quite apparent that a person in the condition in which the patient was could not be held to the same line of conduct as one who was well.

In the testimony of a nonsectarian physician who appeared as a witness the Supreme Court could find no error that warranted a reversal of the judgment. This witness testified that the use of novocaine was harmful, that septicemia is blood poisoning tainting the whole circulatory system, that the toe nails could have been removed to the patient's advantage if it were properly done, and that a general anesthetic should have been used. This testimony was objected to because the witness was not an osteopath and was therefore, it was alleged, not a competent witness on such matters. The defendant osteopath's care of this patient, said the Supreme Court, must be tested by what good osteopathic treatment requires, and by that alone. But even assuming that expert testimony from qualified osteopaths was necessary to sustain a verdict in this case that does not imply that only practitioners of osteopathy could be used as experts at the trial. Many questions pertaining to diagnosis, physical conditions and what they indicate, progress of the infection, and other observed facts and their significance, can be established by nonsectarian practice.

tioners. However, when the propriety of treatment from an osteopathic standpoint is in question, the ordinary physician is not a competent expert, unless it is made to appear that the school to which he belongs and the school to which the defendant belongs require and employ the same treatment. On general matters, this nonsectarian physician could testify. The nearest he came to transgressing the rule was when he said that a general anesthetic should have been used. In this, however he was not attempting to say what good osteopathic practice would require, he was merely stating the medical fact that novocaine would, and a general anesthetic would not retard the plaintiff's circulation. The test is not what school the nonsectarian witness belongs to, but the premises from which he testifies.

The defendant osteopath, as a witness on his own behalf, insisted on characterizing the plaintiff's condition as a case of "local infection." Counsel for the plaintiff however, insisted on calling it "septicemia." The defendant on the witness stand, admitted that local infection and "septicemia" were the same thing. The court itself became involved in the controversy and charged the witness with "hedging" and "butting in." To these remarks of the court, the defendant osteopath objected. Without intending to magnify the importance of this exception, said the Supreme Court we take occasion to say that neither counsel nor the court itself can dictate to a witness the particular terms in which he shall clothe his testimony, unless he uses intemperate and indecent language. If there are two terms meaning the same thing, the witness may choose which one he will use. A cross-examiner, however, is entitled to a frank and direct answer to his proper questions and it is the province of the court to see that he gets it. In the present case, the error of the court if any was committed, was not sufficient to justify a reversal of the judgment.

The judgment of the trial court in favor of the patient was therefore affirmed.

Injunction to Enforce Partnership Agreement—Melrose and Low entered into a contract to practice medicine together. The contract provided that if Low, within the four years covered by the contract severed the partnership relation of his own free will and unprovoked by Melrose and set up practice for himself in Carbon county, the scene of the partnership practice, he should pay Melrose \$5,000 as damages. Within the four-year period, Low did sever partnership relations and set up in practice for himself within the county. Melrose thereupon brought suit for the damages agreed on. He argued, too, that the contract implied a covenant by Low that he would not practice medicine in Carbon county during the four-year period, and therefore he prayed the court to issue an injunction to restrain Low from so practicing. In the course of the trial, Melrose waived his claim for damages, on the assumption that the amount stated in the contract as damages was in fact a penalty and therefore payment would not be enforced by the court. The only remaining relief he asked for was an injunction and that the trial court denied. He appealed to the Supreme Court of Utah.

The findings in this case, said the Supreme Court, were sufficient to support the conclusion that Melrose was entitled to at least nominal damages, if he had not waived his claim to them. Assuming, but not deciding, that the contract in this case implies a covenant limiting Low's practice, Melrose, said the court, is nevertheless not entitled to an injunction.

A writ of injunction can be issued in a case of this kind only to prevent great and irreparable injury to the complaining party. The purpose of such a writ is to protect him from an injury which he will sustain because of the competition of the other party, who has agreed by his contract not to enter into such competition. In this case, said the court, the record does not show even that Melrose is engaged in the practice of medicine, or intends to engage in the practice of medicine, in Carbon county, during the period stated in the contract. The court, therefore, cannot say that Low is competing with him, and if there is no competition there can be no irreparable injury. Furthermore, even assuming that Melrose and Low are striving at the same time for medical practice in the same community, it is possible that Melrose is not being injured by Low's competition. Whether or not competition is injurious depends on a great many facts and circumstances, such as the relative standing of the parties in their profession and in public esteem,

their skill and ability as physicians, the time during which they have engaged in practice in the particular locality and elsewhere, and the amount of business to be obtained in the locality, none of which facts and circumstances are mentioned in the present case. The court ought to be informed concerning the facts and circumstances that make it appear that injunctive relief is necessary to protect the complainant from irreparable injury. Since such information has not been given in this case, the Supreme Court held that the case was not one requiring the issue of an injunction, and the judgment of the trial court in favor of Low was affirmed.—*Melrose v Low (Utah)* 15 P (2d) 319

Workmen's Compensation Acts Aggravation of Pre-existing Arthritis by Accident Compensable—The fact that an employee is suffering from a disease condition does not necessarily bar him from the right to compensation in case of injury and disability. An award may be had for disability caused by an injury arising out of and in the course of employment, if the injury accelerates or aggravates an existing disease. The award in favor of the workman whose arthritis was aggravated by accidental trauma was accordingly affirmed.—*Oklahoma Gas and Electric Company v Slocum (Okla.)*, 15 P (2d) 29

Workmen's Compensation Acts Injury by Wood Alcohol Fumes Compensable—A painter who sprays automobiles with wood alcohol in a small, poorly ventilated room and as a result, in the ordinary course of his employment and without a fortuitous event intervening suffers a disabling illness, is disabled, not by an occupational disease, but by an accidental personal injury and under the Oklahoma workmen's compensation act is entitled to compensation.—*Quality Milk Company v Linde (Okla.)*, 15 P (2d) 58

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be applied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

*Cultivating the Child's Appetite. A C Gipson, Gadsden—p 314

Epithelioma of the Face. C O King Birmingham—p 318

Cultivating the Child's Appetite—Gipson points out that, since hunger is the natural stimulus under which appetite develops it follows that all things which tend to vary the sensation of hunger may have a corresponding influence on appetite. Therefore methods for insuring early and complete emptying of the stomach so that hunger may be felt at the proper time should be instituted. In this regard it is important to avoid eating too much of foods that tend to remain too long in the stomach. Foods rich in fat pass out of the stomach slowly. All fried foods and nuts have this effect and this is the principal physiologic reason for withholding them from a child's dietary. Milk is one of the foods most slowly to be passed out of the stomach. Since milk delays stomach emptying and interferes with the hunger mechanism which one is anxious to stimulate, the advantage of pouring milk into unwilling eaters should be questioned. A long interval should always intervene between meals. It is usually considered that five hours is the best interval between meals of a child more than 18 months of age. The midmorning glass of milk so often given is a bad thing for a child with a poor appetite. Excessive amounts of sweets and starchy foods tend to destroy the appetite. Proteins especially meats, are supposed to stimulate appetite. Broths and meat extracts particularly seem to possess this faculty and are therefore used in the first part of the meal. Carlson has demonstrated that tonics containing bitters have no effect on hunger. Their use in children is disappointing. Treatment of the first attack of anorexia is an important part of the prevention of habitual poor appetite and is almost always necessary during the child's first year. On the first attack of refusal of food the amount should be reduced instead of increased to allow the child time to develop hunger which will stimulate appetite. No child should be forced to eat.

Short PR Intervals and Prolonged QRS Complexes—Wolfarth and Wood believe that, in about 1 out of 1000 electrocardiograms, a case may be encountered that exhibits an abnormally short PR interval associated with a widened QRS complex, markedly aberrant in its initial portion. It is necessary to recognize that this type of tracing may occur in the absence of acquired cardiac damage. Many of these patients are subject to paroxysms of tachycardia and auricular fibrillation. An analysis of the tracings of these cases reveals that their characteristics cannot be explained by the hypothesis that they are due either to bundle-branch block (Wolff, Parkinson and White), or to "paraseptal rhythm" (Pezzi). The abnormal mechanism consists not of a delay or block but of an actual acceleration of the passage of the impulse from the auricle to a section of the ventricle. All the data so far obtained are in keeping with the possibility that an accessory pathway of auriculoventricular conduction (such as that described by Kent, between right auricle and right ventricle) could be responsible for the phenomena manifested by these cases.

Blood Pressure During Attacks of Angina Pectoris—Levine and Ernestine obtained blood pressure readings during spontaneous attacks of angina pectoris in twenty-three patients. In seven, the previous blood pressure readings were known. In three, the attacks were allowed to end spontaneously, and in twenty, relief was obtained by administering glyceryl trinitrate. In every instance the level of the systolic pressure was distinctly higher during pain than when the patient was free from pain. Although this may not be an invariable relationship this study and a survey of the cases recently reported lead one to the conclusion that a failure of the blood pressure to rise in anginal attacks is rare. The authors present evidence to show that in patients with angina pectoris pain alone, e g that of renal colic, does not produce an elevation in blood pressure or bring on an attack of angina. Although they suspect that a temporary elevation in blood pressure is an important factor in the production of anginal attacks and may even be a necessary immediate cause of the attack a final decision as to this relationship will require further investigation.

Heart Block in Coronary Artery Thrombosis—Ball describes a case of transient complete heart block occurring during an attack of acute coronary artery thrombosis. Changes in the ventricular portion of serial electrocardiograms conform to type T₂, indicating myocardial damage as the result of occlusion of the right coronary artery. The transient nature of auriculoventricular dissociation during an attack of thrombosis of the coronary artery has been explained on the basis of the peculiar anatomy of the blood supply to the auriculoventricular node. Permanent heart block without any demonstrable lesions of the node or main stem may be explained on the same basis. The observations in the case presented and a review of similar cases reported in the literature indicate that in patients with occlusion of the coronary artery and complete heart block, the right coronary artery is involved in approximately 93 per cent and the left in 7 per cent. The presence of complete auriculoventricular dissociation is therefore believed to be a valuable diagnostic criterion in the clinical differentiation between right and left coronary artery thrombosis.

Arrhythmia of Heart with Cheyne-Stokes Breathing—Steele and Anthony report a case of heart failure exhibiting Cheyne-Stokes respiration in which various types of cardiac arrhythmia were recurrently manifested during the dyspneic phases of the respiratory cycle. Sinus slowing, prolongation of the PR interval, partial and complete heart block, and, during suppression of the formation of sinus impulses, idiopathic ventricular rhythms were observed. All of these changes in rhythm have previously been found to follow various degrees of vagal stimulation. With the exception of sinus slowing, all the phenomena occurred only after administration of digitalis in effective therapeutic doses. The authors suggest that, since digitalis has usually been administered in cases of Cheyne-

Stokes breathing in which such disturbances of rhythm appeared during the dyspneic phase the vagal effect of this drug is a powerful adjunct in their production

Electrocardiogram Following Ligation of Arteries—In Fowler and his associates investigation, the occlusion of small branches of both the right and left coronary arteries and also the opening of the pericardium without the closure of a vessel produced successive changes in the T wave of the electrocardiogram. In each instance the alteration in the T deflection was associated with a lesion of the myocardium. They believe that electrocardiographic changes of this character are indicative of a myocardial lesion and feel that these observations may be helpful in the diagnosis of occlusion of the smaller branches of the coronary arteries in man

Effect of Ephedrine and Atropine on Heart Block.—Cheer and his associates studied the reactions of two cases of complete heart block to ephedrine. With a small dose of ephedrine, one patient showed practically no change in the auricular or ventricular rate but a moderate elevation of the blood pressure. In the other there was an increase of the auricular rate but practically no change in the ventricular rate or blood pressure. With a large dose of ephedrine one patient showed an increase of the auricular and ventricular rate and a marked elevation of the blood pressure. The ventricular complexes varied and there were frequent ventricular extrasystoles. In the other patient there was a decrease in the auricular rate while the ventricular rate remained constant. There was practically no pressor response and no change in the electrocardiograms. In instances in which slowing of the auricles occurred without any appreciable elevation of blood pressure the slowing may be ascribed to the stimulating effect of ephedrine on the parasympathetic nerves. When an effective dose of atropine was administered to an ephedrinized patient with complete heart block a marked increase of auricular rate and a slight elevation of ventricular rate with a marked elevation of the blood pressure and an increase of the pulse pressure occurred. This action of ephedrine in combination with atropine suggests that atropine neutralizes the parasympathetic effect that results either from the individual's vagotomy or from the stimulating effect of ephedrine on the parasympathetic nerves. Atropine hastened and intensified the pressor effect of ephedrine but shortened its duration and abolished the depressor reflex effect of high blood pressure on the auricular rate. No corresponding effect was noticed when atropine was combined with pseudo-ephedrine. Ephedrine and ephedrine in combination with atropine did not abolish the complete block

left vagal stimulation apparently removed rather than caused such block. The underlying functional disturbance in this case was apparently fatigue of one of the bundle branches, which was sufficiently relieved by increased vagal slowing to permit normal bundle-branch conduction. Abnormal QRS complexes occurred after as long a rest as 0.56 second, and normal complexes were restored by additional rest of 0.08 second.

Treatment of Primary Dysmenorrhea—The treatment of primary dysmenorrhea, still a baffling problem in gynecology, has been rendered difficult because of our ignorance of the factors concerned in its etiology. Novak discusses the constitutional and psychogenic factors that appear to be of prime importance in many cases. Evidence has been brought forward, chiefly from recent physiologic investigations to indicate that the immediate cause of the pain is an exaggerated contractility of the uterus manifested as pain if the pain threshold is lowered or if there is an actual imbalance between the two hormones that appear to regulate this contractility. These are folliculin the normal stimulant of uterine excitability, and progesterin the normal inhibitor. While one cannot of course, discuss these relationships in a precise or quantitative way, the clinical characteristics of primary dysmenorrhea on the one hand and physiologic studies, on the other, both indicate the importance of this hormonal factor in the production of the pain. The treatment of the attack itself, aside from such customary measures as rest, hot applications and analgesics, may rationally include the administration of antispasmodics, such as atropine. Even more intelligent would seem the administration of biologic uterine antispasmodics the one suggesting itself being the luteinizing principle obtained from the urine of pregnant women. This substance readily available has been shown to be like progesterin, a powerful inhibitor of the rhythmic contractility of the uterine muscle.

Treatment of Chronic Peptic Ulcer with Gastric Mucin.—Bloch and Rosenberg relate their experiences with gastric mucin in the treatment of peptic ulcer and point out the advantages and disadvantages over the present orthodox method. From their observations they think that gastric mucin probably acts not through its acid combining power but by virtue of its demulcent effect. Their experience with thirty mucin treated patients, as compared with fifteen ulcer patients receiving other forms of treatment shows that some will not continue its use because of the disagreeable taste and certain untoward symptoms. In others, prolonged administration effects no relief whereas other forms of treatment are successful, such as a diet consisting of pureed fruits and vegetables and other well comminuted foods. In still others relief is temporary and followed by a relapse. In the remainder, relief occurs with mucin when other forms of therapy fail. Further refinements in its manufacture may widen its scope of usefulness in the treatment of peptic ulcer.

Functional Bundle-Branch Block.—Sigler believes that bundle-branch block complete and partial, may be functional in origin caused predominantly by vagal inhibition and fatigue. Restoration of normal QRS complexes in such cases may be accomplished by the removal of vagus inhibition when vagal effect is the underlying cause, and by local rest when fatigue is the cause. The author reports a paradoxical case in which

Lumbar Vertebrae—Rendich and Westing present roentgenograms of five patients who had a fissure within certain of the lower articular processes of the lumbar vertebrae. This fissure about 0.5 mm wide extends transversely and completely through the process at a level approximately 1 cm above the tip. The borders of the bones entering into this formation are regular, well defined and of cortical density. The authors furnish limited data concerning sex age occupation history and clinical observations of their patients. Two patients had accidents just prior to the examination, the other three failed to give any history of old or recent trauma. In endeavoring to explain their roentgenographic observations in the five patients, they consider four possible causes recent fracture, old fracture with ununited fragments ununited epiphysis and accessory bone. The classification of this separate bone particle as an accessory ossicle appears most logical. Such supernumerary ossicles articulating with and actually replacing part of a major bone are not infrequently observed elsewhere in the skeleton. As an example may be mentioned the os trigonum representing the posterior lip of the astragalus. It is their opinion that the

condition is another member of the family of accessory ossicles. For these reasons they suggest the name accessory articular process (processus accessorius articularis).

Skull Changes in Anemias of Childhood—Feingold and Case state that erythroblastic anemia is characterized by definite bone changes. The skull changes in erythroblastic anemia are quite typical. The thin or absent outer table, the thin inner table and the thickened diploe which presents a striated appearance, offer a striking picture. The long bones also show pronounced changes in erythroblastic anemia, as do other bones of the skeleton. Skull changes similar to those reported for erythroblastic anemia have been observed in cases of sickle cell anemia. No definite conclusions can be drawn from the literature regarding changes in the long bones in sickle cell anemia. The authors present the case of a Negro child having skull changes identical with those described for both erythroblastic and sickle cell anemia, but no changes in the long bones were observed. The blood picture showed no normoblasts. Sickle cells were not demonstrated. The skull changes described are indicative of a hemolytic process but are not pathognomonic for either erythroblastic anemia or sickle cell anemia. The occurrence of "turmschädel, or 'tower skull,' has been frequently described in cases of hemolytic icterus. In tower skull the cranial tables are not involved. The characteristic deformity results primarily from a hypoplasia of the base and secondarily from premature synostoses. Tower skull is not pathognomonic for hemolytic icterus but its high incidence in this condition should make it a valuable adjunct in the diagnosis of this disease.

Cervical Glands in Intra-Oral Carcinoma—Stewart presents a review of 257 cases of intra oral cancer treated from 1924 to 1930 at the Steiner clinic excluding the lip cases, 41.3 per cent presented nodes on admission. Of the 189 cases treated prophylactically, nodes developed in 31, or 16.4 per cent. Of the cases treated surgically and radiologically, 70 per cent of the lip metastases were controlled. The combined results of the cancer lesions located in the mucosa of the cheek tongue tonsil, alveolus and floor of the mouth show that only 11.3 per cent were controlled. The cases considered beyond the help of surgery were treated exclusively by radiation. Of these many were palliated but none controlled. The author concludes that metastasis from intra-oral carcinoma is usually to the neck and proves fatal. There is no completely satisfactory therapy, therefore all worthwhile agencies not incompatible with the life of the host must be employed. Surgery alone will give some five-year cures. Irradiation (including interstitial) alone will give a few five-year cures. The correct combination of surgery and irradiation should give better results than either alone. All workers should report their method of treatment and results so that patients may have the benefit of the best therapy.

Intra-Oral Cancer—The material for Fischel's study comprises 190 cases from the Barnard Free Skin and Cancer Hospital and 50 private cases. Every patient had more or less radical resection of the lymph nodes of the neck as part of the treatment of some form of intra-oral carcinoma, including carcinoma of the lower lip in the hospital group. In many instances resection of the lymph nodes was combined with an intra-oral operation. In this group the operative mortality was from 20 to 25 per cent. The percentage of deaths from radical resection of the glands of the neck alone was approximately 4 per cent. From a five-year cure standpoint, analysis of both private cases and free clinic cases showed a striking difference in the number of patients alive when no carcinoma was found microscopically in the excised lymph nodes. Of the 30 clinic patients without carcinoma in the glands 19 survived for five years. Of 32 patients with carcinoma of the glands, 8 were alive five years later. These are exclusive of lip patients. Of 66 lip patients 38 of 40 without carcinoma survived, of 16 with carcinoma 9 survived. These figures are based on records that are complete and patients who died as a result of operation are excluded. The significant facts are that the percentage of patients alive five years on whom neck dissections were done before the glands were involved is much greater than that of the patients in whom the glands showed carcinoma, and that of 48 patients in whom carcinoma was demonstrated as having formed metastases in the cervical lymph nodes, 17, or 35 per cent were alive without recurrence five

years later. These results cannot be approximated in the case of proved metastases to lymph nodes by any form of treatment other than radical surgery.

Intra-Oral Carcinoma—Duffy draws the following conclusions from a study of 1,363 patients with intra-oral carcinoma, of whom 70 per cent were admitted to the hospital without palpable nodes, 175 had operable nodes and 205 patients presented inoperable nodes. A large proportion of the cases presenting intra-oral carcinoma are admitted to the hospital without metastases to the cervical lymph nodes. A few patients admitted without cervical lymphatic metastases develop metastases in that region. The patients without cervical metastases, and those with inoperable metastases, constitute most of the cases admitted to the hospital. Palpable nodes in the cervical region are often hyperplastic nodes. Differential diagnosis is difficult. Errors in diagnosis are more apt to be made in diagnosing hyperplastic nodes as metastatic, rather than metastatic nodes as hyperplastic. Operability of the cervical nodes is determined not only by the stage of the metastases but also by the grade of the malignant condition of the primary lesion. Conservatism is maintained at the Memorial Hospital in the care of patients without cervical lymphatic metastases, and the field of operable nodes is being narrowed as experience is gained in the use of gold tubes in the advanced and borderline cases of cervical metastases from intra-oral carcinoma.

Comparison of Neoarsphenamine and Arsphenamine—Thornley presents a statistical study of 999 syphilitic patients who received neoarsphenamine or arsphenamine and states that the difference in the efficacy of neoarsphenamine and arsphenamine is not great when neoarsphenamine is given well diluted in moderate dosage, and by the gravity method. The reactions are so much less by the gravity method that this fact should more than counterbalance the convenience of the syringe method. Considering the high number of reactions reported by other clinics and by physicians in private practice in which neoarsphenamine is given by the syringe method, against the incidence of 9 per cent noted with the gravity method, all the advantages that have been claimed for neoarsphenamine because of the possibility of giving it with a syringe are absolutely nullified. Neoarsphenamine given with a syringe will cause complications. On the other hand if it is given well diluted and by the gravity method, the results will be nearly as good as those obtained with arsphenamine and there will be fewer complications.

Hyperglycemia in Diseases of Skin—Tauber made a study of determinations of the blood sugar in more than 1,500 persons and of blood sugar tolerance tests in about half that number. The total series consisted of 514 diabetic patients, 504 patients suffering from a variety of causes and 511 dermatologic cases. His observations were contrary to the statements made

in the literature that common disorders of the skin are associated with hyperglycemia, as he found, almost without exception, that the blood sugar is normal and that in furunculosis the reverse of hyperglycemia is the rule and the fact. That certain groups of cutaneous diseases are connected regularly with hyperglycemia is doubtful. He believes that dextrose given intravenously, combined with a high carbohydrate diet, is almost a specific in the cure of furunculosis.

Exfoliative Dermatitis and Malignant Erythroderma—Montgomery's study of seventy-three cases of exfoliative dermatitis and sixteen cases of generalized erythroderma includes cases of exfoliative dermatitis of the primary or idiopathic type (Wilson) and cases secondary to various types of dermatosis, such as psoriasis, eczema, seborrheic dermatitis and lichen planus. He states that the histopathologic picture in erythroderma psoriaticum is diagnostic or at least suggestive of psoriasis in most cases, provided a suitable site for biopsy is chosen. Exfoliative dermatitis secondary to other benign conditions can usually be distinguished from psoriasis and from lymphoblastoma. About 25 per cent of the cases of exfoliative dermatitis proved, on microscopic examination to belong in the group of lymphoblastomas. The type of etiologic factors concerned in exfoliative dermatitis cannot be diagnosed on the basis of objective examination only. It is often necessary to use all the means at one's disposal, including biopsy of the skin and lymph nodes, roentgen rays, studies of the blood and prolonged periods of observation, in order to arrive at the correct diagnosis. Mycosis fungoides may start as exfoliative dermatitis, only later to assume its more common clinical appearance. In several cases of exfoliation or universal malignant erythroderma, primary specific changes of one of the types of lymphoblastoma were found in the skin before such changes were seen either at biopsy of a lymph node or in the course of studies of the blood. The histopathologic report that an excised lymph node presents merely an inflammatory reaction does not rule out the possibility that the exfoliative dermatitis may be of lymphoblastomatous etiology. Although the cutaneous histopathologic picture in exfoliative dermatitis and malignant erythroderma may present the features of lymphoblastoma, in more than half of the cases it is impossible definitely to specify which type of lymphoblastoma will eventually develop. In a few cases the cutaneous manifestations cleared up, only to return in another form after a variable period or remission.

- Metastatic Sarcoma of Choroid. Report of Case. W. E. Fry. Philadelphia—p. 248.

Ocular Tuberculosis—According to Friedenwald's experiments, practically complete desensitization of tuberculous guinea-pigs can be achieved by daily injections of massive doses of tuberculin. Guinea-pigs immunized to tuberculosis and sensitized to tuberculin by inoculation with an avirulent strain of tubercle bacilli, and subsequently desensitized to tuberculin show no diminution in their resistance to reinfection as tested by the mortality of the disease, the spread of the infection or the progress of the local lesion. In all these respects, the desensitized animals showed more resistance to reinfection than did nondesensitized controls. Allergy in tuberculosis cannot be regarded as essential to immunity. The rationale for the use of tuberculin in treating tuberculous infection is therefore the production of perifocal desensitization rather than perifocal allergic reactions. When sufficient numbers of tubercle bacilli are injected into the anterior chambers of guinea-pigs immune to tuberculosis and allergic to tuberculin, an acute fibrinous iridocyclitis is produced which usually subsides in from two to four days. This reaction is analogous to the Koch reaction in

the skin. The clinical picture of tuberculous kerato-iritis as seen in human beings can be reproduced in guinea-pigs by the inoculation of living tubercle bacilli into the anterior chambers of animals previously immunized by subcutaneous injection of avirulent organisms. Similar inoculation of nonimmune animals produces a rapidly caseating lesion unlike anything seen clinically in human beings. Partial desensitization of guinea-pigs allergic to tuberculin can be achieved by daily massive injections of sterile glycerin broth.

Ocular Syphilis—Drake points out that acute syphilitic meningitis and meningo-encephalitis are relatively rare but their presence should be considered in any patient presenting signs of meningeal involvement. Papilledema is an important clinical sign in this disease and should be searched for in all cases. It was present in sixteen of the fifty cases reported in the literature. The degree of papilledema in these sixteen patients ranged from 2 to 5 diopters, and the swelling involved both optic nerves in fourteen cases. Papilledema in this disease responds to antisyphilitic treatment, in some cases, however, a postneuritic atrophy remains. Contrary to the opinion of many observers, this disease process often develops in those cases in which there has been no previous antisyphilitic therapy. Previous insufficient antisyphilitic therapy, especially arsphenamine, therefore, is not necessary for the development of acute syphilitic meningitis. Headache, cervical rigidity and paralysis of the cranial nerves were the most prominent symptoms. Acute syphilitic meningitis and meningo-encephalitis respond well to early and intense antisyphilitic therapy. Of the fifty cases reviewed from the literature, forty occurred in male patients. The average age was 27.2 years, the youngest patient's age was 1 year and the eldest 49 years. The mortality was 22.2 per cent.

Perirenal and Renal Hematomas—Polkey and Vynalek present the 178 cases of renal hematomas collected from the literature and state that 76 per cent of their experiments on animals with ligation of the renal vein were positive for perirenal hematoma, and 100 per cent for parenchymal hemorrhage. Of the 178 assembled cases, almost 70 per cent showed renal and suprarenal disease associated with perirenal hematoma. The causative disease of the kidneys, suprarenals, blood vessels and infections are all capable of sudden congestions of the organs and elevation of intrarenal tension. Spontaneous perirenal hematoma may often be the result of sudden congestion of a diseased organ. The authors report a case that was due to an extrarenal cause. Nephrectomy is the operation of choice in cases of renal bleeding. Spontaneous cases in which no

cause is discovered are probably explained by a sudden renal congestion, acting on some pathologic condition of the kidney or of the perirenal tissues. Even in the cases with a demonstrable cause, the mechanism of hemorrhage may be as suggested.

Acute Pancreatitis—Haynes describes an operation for drainage from the posterior surface of the pancreas, in which the main advantages of the procedure are that it affords (1) a better opportunity to palpate the gland thereby yielding a clearer conception of the pathologic changes and points where drainage is most essential (2) better drainage (more dependent drainage) (3) less hemorrhage (4) fewer postoperative adhesions, and (5) easier performance. None of the author's five cases of drainage from the posterior surface have presented any symptoms that could be attributed to lack of drainage. If drainage is the chief object of the operation it seems that this method has decided advantages over any other method that he has been able to find. In no case has it been necessary to clamp or ligate any bleeding points about the pancreas.

Madura Foot—Gellman and Gammel report a third case of monosporosis under the clinical picture of Madura foot of the white grain variety occurring in a native American. Mycetomas due to higher fungi rarely respond to medical treatment (iodides and compound tincture of iodine given intravenously), therefore they belong to the domain of surgery. In cases of chronic osteomyelitis and tuberculosis or syphilis of the bone, the possibility of a mycosis should be considered. Monosporium apiospermum injected into the knee joints of rabbits results in a purulent arthritis with periarthritic abscesses from which retrocultures are positive. This is the first instance in which experiments on animals carried out with a fungus isolated from a patient with maduromycosis in the United States yielded positive results.

Surgery of Pulmonic Valve—Powers and Bowie performed electrocoagulation of the pulmonic valve on six dogs and followed it with intravenous inoculation with cultures of *Streptococcus viridans*. Acute vegetative endocarditis developed on the traumatized valve. As these lesions healed the cusps of the valve became thickened, fibrous and inelastic; the edges tended to adhere to one another, and the end result was actual stenosis of the pulmonic orifice. Two of these animals with experimental pulmonic stenosis were subjected to partial resection of the stenosed valve. The operation was well tolerated, and the animals lived for twenty months without evidence of cardiac decompensation. The authors suggest that the condition, in certain selected patients with congenital pulmonic stenosis, may be amenable to surgical treatment.

*Use of Digitalis in Pneumonia. H. B. Cason, Jr. Warrenton—p. 64.

Use of Digitalis in Pneumonia—Cason points out that of late the statistical evidence is against the routine use of digitalis in pneumonia. In the usual case the symptoms of heart failure are due primarily to toxemia and anoxemia and digitalis having no effect on these primary causes will be of no benefit in neutralizing their actions. A possible harmful effect may be due to stimulation of the vagus and cardioinhibitory center. The use of digitalis in pneumonia should be confined to cases of auricular fibrillation and auricular flutter and to cases of decompensation or previous to decompensation, and then only after careful thought and consideration.

Thyroid Deficiency in Arthritis—Hall and Monroe analyzed 300 patients with chronic nontuberculous arthritis in order to detect the signs and symptoms of thyroid deficiency, the basal metabolic rates, the action of thyroid therapy and the results of medical treatment, which included thyroid substance. Of these, 150 were of the atrophic type of arthritis and 150 were of the hypertrophic type. In the hypertrophic group of patients 1 The symptoms and signs of hypothyroidism occurred with great frequency, with no other obvious explanation for them 2 The basal metabolic rates were below minus 10 in 50 per cent and below minus 15 in 34.2 per cent of 108 patients, even though most of them were determined under inadequate conditions of rest and in the presence of pain. In forty-two patients no basal metabolic rate determinations were made. 3 They were for the most part well nourished persons and no other explanation for the hypometabolism was apparent except for the glandular deficiency 4 Thyroid therapy was of permanent beneficial effect in 49.1 per cent of 116 patients in whom it seemed wise to use it. In the atrophic group of patients 1 The symptoms and signs of hypothyroidism were encountered less frequently and generally would be accounted for on a basis of depletion and undernutrition 2 The basal metabolic rates were below minus 10 in 35.6 per cent and below minus 15 in 17.7 per cent of 106 patients. No basal metabolic rate determinations were made in forty-four patients 3 Definite glandular deficiency seemed present in only a small number, and there was usually another explanation for the hypo-

metabolism 4 Thyroid therapy was of permanent beneficial effect in 16.5 per cent of 103 patients in whom it seemed wise to use it. The authors conclude that thyroid deficiency appears to be a contributing etiologic factor in certain patients with chronic arthritis, as well as infection, dietary deficiency, trauma and depletion. Its correction, when present improves the general well being of the patient, aids in the relief of joint pain and disability, and helps to lay a foundation for permanent control of the arthritis, probably through better joint nutrition.

Skin Capillaries and Vitamin C Standard—Göthlin states that the strength of the skin capillaries can be systematically ascertained by the modifications he made in the clinical capillary test to transform it into a test of the strength of the capillaries satisfactory from the physical point of view. In performing the test the veins of the upper arm must be subjected to manometrically measured pressure, and in most cases more than one degree of pressure must be applied to make the determination. Each degree of pressure applied should be lower than the diastolic blood pressure in the brachial artery of the subject of examination. Otherwise the afflux of arterial blood is also partly obstructed. The skin area within which the observations are to be made should be definitely limited as to position, shape and size. In the author's method pressures of 35 and 50 mm of mercury were selected. The skin area to be examined is circular, with a diameter of 60 mm., and its center coincides with the center of the hollow of the elbow. In order to obtain sufficient sensitiveness in this test it is necessary to maintain the pressure for fifteen minutes. In carrying out the test it proved advisable to fix limits between the various grades of strength in the following manner, according to a descending scale: grade I no petechiae within the examined skin area at a pressure of 50 mm of mercury in fifteen minutes, grade II petechiae appear at a pressure of 50 mm of mercury but their number does not exceed 6, grade III, more than 6 petechiae appear at 50 mm of mercury but none or at most one at 35, and grade IV, at least 2 petechiae are present at a pressure of 35 mm of mercury. The capillary strength, ascertained by this method, indirectly reveals the vitamin C standard of persons who are healthy or exhibit only such deviations from health as are in themselves due to a low vitamin C standard. The author suggests that with the same method it is probably also possible to estimate the individual vitamin C standard in cases of uncomplicated arteriosclerosis, afebrile tuberculosis, achylia and uncomplicated afebrile gastric ulcers. The method may be used as a test of the individual vitamin C standard by physicians, hygienists and dentists in their practice. It can also be used in the statistical examination of groups (e. g., in the army, boarding schools, orphanages, old people's homes, asylums and prisons) in order to ascertain whether the diets in use provide a sufficient supply of vitamin C.

Blood Nonprotein Nitrogen and Creatinine in Nephritis—Cantarow and Davis made simultaneous determinations of nonprotein nitrogen and creatinine of the blood of 112 patients with nephritis and eighty patients with urinary obstruction due to prostatic hypertrophy, in all of whom nitrogen retention was present. They observed that, contrary to some previously reported observations, the degree of creatinine retention was practically the same in the two groups of patients. With total nonprotein values below 130 mg per hundred cubic centimeters the average increase in blood creatinine was slightly greater in the obstructive than in the nephritic group. It appears that no distinction can be made between purely obstructive urinary lesions and actual renal disease on the basis of the relative degree of blood creatinine elevation.

Method of Preparing Blood Smears—Kato describes what he believes is a proper method for the preparation of smears in routine examination of the blood, as well as in a study of the morphology of the blood cells. A drop of blood flowing from a fresh stab wound is received on a clean slide. The optimal size of the drop should be from 3 to 5 mm. in diameter when received on the slide. The position of the drop should be slightly to one side away from the center of the slide. An oblong cover glass 24 by 50 mm., is laid immediately over the droplet and the blood is allowed to spread between the cover glass and the slide into a circle of thin film by the weight of the cover glass. When the blood has spread into a circle of appropriate dimension, the cover glass is quickly drawn across toward the other end of the slide. This will give an

elongated oval of thin film the border of which should be well within the edges of the slide. The slide should be fanned at once and air dried in the usual manner. The film so prepared will be found to have an even distribution of the leukocytes in almost every microscopic field. The erythrocytes will also be found to be spread in a single layer without overlapping or rouleaux formation.

Infantile Eczema.—Koch and Schwartz present the results of 103 cases of infantile eczema treated at the Milwaukee Children's Hospital. Of the 103 patients, 15 died, a mortality rate of 14.5 per cent, and 45 developed one or more complications, a morbidity rate of 43.6 per cent. Of 56 infants with infantile eczema admitted for eczema alone, 10 died, a mortality rate of 17.9 per cent, and 33 had complications, a morbidity rate of 58.9 per cent. Infants having infantile eczema should not be admitted to an infant ward if they can possibly be treated in a home or foster home supervised by an outpatient department, utilizing the Speedwell technique of Chapin. Sudden death in infantile eczema may be the result of massive respiratory infection of hematogenous origin.

Constitutional Treatment of Ocular Syphilis.—According to Greene, early and vigorous treatment must be started in all cases of ocular syphilis. Arsenicals are the best therapeutic agents in the treatment of ocular conditions, aside from optic nerve involvement. A negative Wassermann reaction is not conclusive evidence that the patient is not syphilitic. Arsenicals in the treatment of optic atrophy or neuritis must be used with great caution. Many cases of latent syphilis would do better if arsenicals were not used. In acute syphilitic ocular

conditions, palliative treatment with mercury by mouth or small doses of iodides by mouth is inadequate. Such procedures have been criticized and the criticism is justified. Antisyphilitic treatment is often of great value in the treatment of apparently nonsyphilitic conditions.

Treatment of Chorea.—Robinson believes that most chorea patients do better in bed in an atmosphere free from all influences that tend to stimulate the emotions. In the sthenic cases, the bed should be made on the floor or in a padded crib, bony prominences should be protected by packing with cotton wool. In feeding the patients metal feeding utensils should be employed. Elimination should be stimulated. The medical treatment consists of sedatives to quiet restlessness and hypnotics to aid sleep. Chloral phenobarbital and bromides may be used. The author states that acetylsalicylic acid is as specific in the treatment of chorea as quinine is in tertian malaria. He has seen all movements cease in the most severe cases within a week or ten days. He has never seen a mild case of chorea become severe if this treatment was instituted during the mild stage. He has seen many patients with sthenic chorea, under arsenic treatment for weeks and even months with no benefit symptomatically, get well after a week or ten days of acetylsalicylic acid treatment. It may be given in from 5 grain (0.3 Gm.) doses every two to three hours up to 30 and 60 grains (2 and 4 Gm.) daily. It is well to give an equal amount of sodium bicarbonate with each dose. In the treatment of chorea by this remedy it is necessary to give enough in order to get good results. Children can take quite large doses of acetylsalicylic acid with safety. Lees in the Harvey lecture of 1903 said that he was in the habit of giving as much as 100 to 300 grains (6.5 to 19.5 Gm.) of sodium salicylate daily to children from 6 to 10 years of age, rarely with any evidence of intoxication. If symptoms of intoxication appear the dosage should be decreased. Acetylsalicylic acid should be continued for at least a week after the choreic symptoms have disappeared and be given in gradually decreasing doses. After discontinuance it is well to give the child some tonic medication. Syrup of ferrous iodide is an excellent tonic for children.

Treatment of Common Leukorrheas.—King states that there are only three possible sources of the common leukorrheas: the endometrium, cervix and vagina. It is now known that the endometrium rarely produces a discharge except in acute specific or nonspecific infections. For the purposes of this discussion, therefore, discharge from the endometrium may be ignored. There remain for consideration two sources of leukorrheal discharge, the cervix and the vagina. As the type of discharge from each has well defined characteristics, they should be distinguished as cervical leukorrhea and vaginal leukorrhea. In the treatment of cervical leukorrhea the removal of the glands by coning out the cervix and infolding the cer-

vical shell as proposed by Sturmdorf is an improvement over amputation. Destruction of the glands by other than surgical means can be accomplished effectively in three ways: the nasal loop cautery, surgical diathermy and electrocoagulation. The nasal loop cautery requires the least expenditure for apparatus and with a little experience its use is highly satisfactory. Surgical diathermy is in some respects an improvement over the cautery. It is more positive in action and somewhat better controlled. Electrocoagulation is a still simpler procedure. A bipolar applicator designed for the purpose is inserted into the canal, the current applied and the applicator rotated. The amount of current and length of application will determine the depth of coagulation. Douches in cervical leukorrhoeas, while in no sense curative, do contribute to the patient's comfort. An alkaline douche aids in clearing the vagina of collected mucus. It should be a douche that is nonirritating and astringent and one that has antiseptic properties. Such an agent is found in zinc chloride. The patient is given a solution containing from 30 to 45 Gm of zinc chloride in 240 cc of distilled water. To this is added 1 cc of hydrochloric acid to aid solution. Of this 8 cc is used in a quart of water at night just before retiring. In severe cases a morning douche may also be taken. The author states that the liberal use of a powder in the vagina and the insertion of an elongated absorbent tampon is also a satisfactory method in treating vaginal leukorrhoeas. The powder aids in keeping the vagina dry and the tampon separates the vaginal walls and absorbs any exudate. The tampon remains in the vagina from twelve to twenty-four hours and its removal is followed by a douche. These treatments may be given every three or four days. Many powders may be used but the writer prefers one composed of equal parts of mercurous chloride, boric acid and bismuth subnitrate.

Choice of Treatment in Acute Empyema—Eggers points out that the proper treatment of empyema in all its phases requires a knowledge and an appreciation of the physiology of normal respiration and also of the variations in the presence of disease. No one method will always give uniformly good results and no attempt should be made to make a case fit a given method of treatment. On the contrary that treatment which will most likely restore the patient to health in the shortest time should be adopted in each case. There is a common type of empyema, following pneumococcus pneumonia, in which the pus collects in the lower part of the chest. It becomes walled off early and the costopleural angle becomes obliterated by adhesion of the diaphragm to the chest wall. Intercostal incision in the eighth or ninth space or the resection of a portion of the eighth or ninth rib will place the drainage at the dependent part of the cavity. Simple open drainage or the addition of irrigations preferably with surgical solution of chlorinated soda constitutes the after-treatment. The majority of empyema cases conform to this type. Taking this as a basis, one may modify the treatment as indicated in a given case. If there is an unusually large amount of fluid as is so often found in the septic streptococcus cases, and it is felt that the presence and absorption of this fluid itself, regardless of the stage of the pneumonia, is dangerous to the patient, one of two courses may be followed. 1 The fluid may be aspirated and this may be repeated as often as the thorax refills, until the pneumonia has subsided. Coincident with resolution the fluid has usually become pus and has become walled off. A simple drainage opening may then be made and the case treated as a pneumococcus empyema. 2 If more urgent treatment is demanded, one may establish closed drainage either by means of the trocar catheter method or by the insertion of a tube through an intercostal incision. Irrigations may be added. One may continue this method until a cure results or only sufficiently long to bridge over the period of emergency and then convert the drainage into an open one. The aim is to keep the cavity empty and to bring about sterility. This sterility is best obtained by open drainage perhaps favored by irrigation with antiseptic solutions. The author believes that the only safe healing for an empyema is by obliteration of the cavity. The two opposing layers should adhere, and they will adhere just as soon as the surfaces are sterile. Such an obliteration is the best guaranty against recurrence and chronicity.

Treatment of Empyema Thoracis by Packing—Connors presents the results in twenty-three cases of empyema thoracis

and in eleven cases of other types of pleural suppuration in which the pleural cavity was packed with plain gauze. This is prepared from the wide bandage roll by folding it longitudinally until it is about two inches wide. The amount of gauze used varies with the size of the cavity. In some cases the author has used as much as thirty yards. He has abandoned the use of iodoform gauze because in a few cases it seemed to produce toxic symptoms, was more expensive and proved no more efficacious than plain gauze. With curved sponge forceps the gauze is introduced into the cavity, particular attention being paid to the region of the apex of the lung and to the sulci formed by the lung and the chest wall. The entire cavity is filled and firmly packed by digital pressure. The edges of the skin wound are held apart by gauze and the cut surfaces are protected by petrolatum gauze. A dry dressing completes the procedure. The author removed the packing in two days in his series of twenty-three patients and replaced it with fresh packing in only one instance. He mentions the following advantages of the packing method: 1 The pleural cavity is cleaned within twenty-four hours and remains grossly clean until the cure is effected. 2 The postoperative management can be easily handled by the surgeon. 3 The introduction of tubes is unnecessary and therefore a source of pleural irritation is removed. 4 It prevents the discomfort that may be due to a mobile mediastinum by fixing it. 5 The large thoracotomy wound with the help of the Cameron light permits a perfect inspection of the pleural cavity and allows the operator to remove all fibrin and break up the necessary adhesions and pockets. 6 And not the least interesting is that it has allowed a clear view of the mechanism of the cure of the empyema cavity and has helped improve the methods directed toward cure.

Sterilization of Surgical Catgut Sutures—In an investigation extending over two and one-half years, Clock prepared

several thousand catgut sutures from 334 lots of catgut. Twenty-seven different chemical compounds were used for treating these various lots of catgut under a wide variety of conditions, in an attempt to bring about chemical sterilization the various chemical treatments having been applied to catgut ribbons and raw catgut strings as well as to artificially infected catgut. Throughout his experiments he used the standard bacteriologic test, devised and proposed by Meleney and Chatfield, for determining the sterility of catgut, he also used three additional controls for safeguarding the reliability and efficiency of the test. The results of his experiments with copperized catgut sutures demonstrated that copper salts applied to catgut by the von Linden method do not effectively sterilize catgut. His copperized catgut experiments have shown that copper salts exert a bacteriostatic action on the bacteria in catgut, for, when the copper is removed with a suitable neutralizing fluid the bacteria become reactivated. He observed that a 1 per cent solution of sodium thiosulphate and sodium carbonate will not remove copper salts from catgut sutures. A solution consisting of 5 per cent ammonium chloride and 0.5 per cent ammonium hydroxide was found to be an effective neutralizing agent for dissolving and removing copper salts from catgut. Copperized catgut sutures embedded in animal tissues were less readily absorbed and were definitely more irritating than plain catgut sutures. Chemical analyses of catgut sutures of three American manufacturers and one German manufacturer revealed appreciable quantities of copper. Bacteriologic examinations showed the presence of living bacteria in 42 of 156 of the copperized sutures of the three American manufacturers, and in 19 of 36 of the copperized sutures of German make. Peppermint oil catgut sutures were demonstrated by repeated bacteriologic tests to be 100 per cent non-sterile. This method of sterilizing catgut not only fails to sterilize artificially infected catgut but even the ordinary raw catgut made from fresh sheep intestine and processed under ideal sanitary conditions. Bacteriologic tests applied to commercial catgut sutures containing a large amount of a mercury compound have shown that arrested development of bacteria within the catgut is brought about through the bacteriostatic action of the mercury compound. These tests have also proved that removal of the mercury compound from the sutures, by means of a suitable neutralizing fluid reactivates the bacteria, which then are able to grow in the culture medium. The author concludes that a suitable neutralizing fluid must be devised and used to dissolve and remove the particular chemical substance found in the catgut sutures, before the standard bacteriologic test is applied. Carefully controlled heat sterilization is the only uniformly reliable and positive method of sterilizing surgical catgut sutures.

Streptococcic Infection of Peritoneum.—In his experiments on rabbits, Smith found that a high degree of immunity to intraperitoneal inoculation with a toxigenic, moderately virulent scarlatinal streptococcus can be produced by the administration of specific antitoxin. This immunity seems to depend on the neutralization by the antibody of toxin produced by the infecting organism *in vivo*, and the resistance of the body to the infection, which is facilitated by the elimination of the toxic factor, is manifested by an increase in temperature, a local and general mobilization of leukocytes, and the removal of the invading bacteria from the peritoneal cavity and blood stream by phagocytic cells. The immunity conferred by the prophylactic administration of antitoxin enables the animal body to survive the acute phase of a disease which is rapidly fatal for the unprotected control, but even this high degree of antitoxic immunity is not sufficient to prevent the development in a certain percentage of cases, of later chronic infections. The therapeutic use of antitoxin has definite limitations. The administration of the antitoxin after the onset of the infection appears to enhance the defensive powers of the body however, and may be followed by a completely successful resistance to the bacterial invasion and recovery. The author's experiments substantiate the view of Downie that toxin aids the establishment of streptococcic infection by inhibiting phagocytosis. The highest degree of passive antitoxic immunity in streptococcic infection of the peritoneum is produced by prophylactic administration of the serum. In the therapeutic use of antitoxin it would seem however that the administration of the serum early in the disease might confer a protection comparable to

that produced by prophylactic injection. Early therapeutic administration of antitoxin should restrict tissue invasion to a minimum and thereby limit the possibility of infections of a focal nature developing as complications.

Treatment of Acute Intestinal Obstruction.—Elman states that the cause of death in untreated complete high obstruction (stomach and duodenum) is probably a physico-chemical one due to a depletion of water and salts from the blood into the vomitus or obstructed contents. The resulting dehydration can explain all of the so-called toxic symptoms. Treatment with a modified Ringer's solution effectively restores the blood to normal, improves symptoms, and permits adequate surgical treatment without great risk. The cause of death in low intestinal obstruction (ileum and colon) is probably different but as yet there is little convincing evidence that a 'toxemia' is present. Distention plays a prominent part and the idea is expressed that sudden release of distention may be an important factor in the fatal outcome. The operative treatment in late cases of obstruction should be confined to gradual decompression of the distended intestine strangulated intestine being merely exteriorized for later removal.

Congenital Hypertrophic Stenosis of Pylorus.—Lanman and Mahoney regard pyloromyotomy as the treatment of choice in congenital hypertrophic stenosis of the pylorus. They believe that their analysis of 425 cases establishes its safety. Because the mortality and morbidity are greater in the age group of 6 weeks and over in which there has been a longer duration of symptoms and treatment, they advise operation as soon as the diagnosis is established. The shorter the period of symptomatology, the better is the operative risk. The safety of surgical treatment of pyloric stenosis depends on the close observance of many details. This includes 1 Combating and overcoming the loss of body fluids before and after operation. The measures to be used are dependent on the degree of dehydration; the degree of dehydration will be greater in cases in which there has been a longer duration of symptoms. 2 Especial care should be taken in preventing loss of body heat before, during and after operation. 3 The greatest care should be exercised in controlling hemorrhage at operation. Rigid asepsis and painstaking approximation of the abdominal wound are necessary. 4 In incising the "bloodless" area of the pylorus one should be sure that all constricting fibers are divided, using especial care not to perforate the mucosa of the pylorus at the duodenal end. It is safer to use blunt dissection in completing the division and spreading of the serous and muscular coats. 5 Hemorrhage from the pyloric incision that is not controlled by hot saline packs must be controlled by suture with or without the use of a piece of rectus muscle. 6 The care during the first four or five days following operation must include maintenance of the fluid requirements by methods supplementary to what can be administered by mouth. The caloric needs usually cannot be met for these first four or five days following operation and it is unwise to attempt to do so. If the fluid requirements three ounces per pound of body weight, are met the caloric intake is of minor importance during this short period. 7 Ether by the open drop method is the best and safest anesthetic.

Carcinoma of Cervix.—Schiller believes that it will be possible essentially to improve results in general in regard to carcinoma of the cervix. The method of iodine painting is easy and cheap; a physician can examine from twelve to fifteen women in an hour's time or seventy-five women in a forenoon, five hours. It should be considered a matter of course and it should be one's duty to examine for incipient carcinoma every patient coming for treatment. It is a fact that in early carcinoma, there is no subjective symptom which would force a woman to interview her physician, but experience has taught that if a patient is forced to see her physician because of other troubles such as fibroids, disease of the tubes or discharge, it is only through routine and thorough examination that the cancer is incidentally discovered. There are patients who seek treatment at hospitals because of some gynecologic condition and who on examination are found to be harboring an early carcinoma of the reproductive organs. This condition could be remedied if every woman would have a routine test by the iodine painting method twice or three times a year. It would then be possible to locate a carcinoma of the cervix in its earliest stages and treatment could immediately be instituted.

that would raise the proportion of complete healing to 95 or 100 per cent, especially with the improvement of postoperative roentgen treatment. Such a routine examination would not involve great expense and would not require especially instructed men. The technic used in painting the cervix is as follows. A cervical speculum is placed in the vagina, and with a long spout about 10 to 15 cc of compound solution of iodine is poured and spread with a tampon over the cervix and left in the vagina for about a minute. The solution is then absorbed with a tampon, and the cervix and vagina are cleaned of the excess liquid, and gently wiped. The solution should moisten the entire cervix and no fold should prevent the entrance of the liquid. If the epithelium shows an unstained spot, one must look for cancer and the tissue must be examined histologically. The presence of white, unstained epithelial spots may indicate four possibilities: (1) the presence of carcinomatous layers or incipient carcinomas, (2) the presence of hyperkeratosis, a result of prolapse or descensus vaginae, (3) the presence of hyperkeratosis, a consequence of syphilitic infection, and (4) the desquamation of the upper layers of glycogenous epithelium, which may have been caused by the touching of the cervix with sharp instruments or by the rough insertion of the speculum. Such traumatic desquamations are easily to be diagnosed by their form, as they resemble narrow sharp and straight line scratches.

Nephritis, Nephrosis and Edema.—Hodges discusses the suggestion of Addis that the term "Bright's disease" be applied to renal lesions that do not show inflammation of the kidney. Addis found that the most constant changes in chronic interstitial nephritis which could be approached from the clinical standpoint were to be found in the urinary sediment. He found that the hemorrhagic forms show a predominance of red cells over the white and epithelial cells, while in the degenerative forms, the white and epithelial cells predominate over the red ones. The author states that more than 40 per cent of renal function is lost before the nitrogenous elements in the blood are increased. He has found the test diet of Mosenthal satisfactory and practical. It shows earlier changes than the blood chemistry. In the late stages, the blood nitrogen retention is the more important. He emphasizes the importance of feeding the proper amount of protein in chronic interstitial nephritis. The catabolic protein products should be limited to the capacity of the kidneys to excrete them, but at the same time the anabolic needs should be satisfied, as well as the replacement of the proteins lost in the urine. Too great restriction of proteins often causes anemia, weakness and other concomitant symptoms without benefiting the chronic interstitial nephritis or lowering the blood pressure. Blood cells in the urine in more than normal amounts rule out nephrosis and add the glomerular element. An alkaline ash increases and an acid ash decreases the production of edema. The edema fluids in cardiac, nephritic and nephrotic patients can be differentiated by their protein content. The blood protein is an important

element in maintaining the osmotic pressure of the blood. A marked loss of blood protein results in the development of edema. The disappearance time of intradermally injected physiologic solution of sodium chloride is a valuable aid in the prognosis and in the therapeutic management of nephritis with edema.

Prevention of Measles by Convalescent Serum.—Hunter administered 5 cc of convalescent serum to 233 patients definitely exposed to measles, 185 entirely escaped infection, giving a protection rate of 80 per cent. In 36 cases the attack was attenuated. In 28 of these the infection was contracted from the original case of measles, and 6 from a subsequent or "primary" case or from a coincident "normal" case, while in 2 cases measles was later reported to have developed beyond that period. Clinically, there was a striking difference in the type of attack after such a small dose as 5 cc., even up to the eighth or tenth day of exposure. Of all the patients who developed measles after serum inoculation not one was really ill, and, in fact, many cases would not have been reported had not the slightest appearance of any sign been noted as evidence of infection. It appears that the best method of utilizing the serum is not to prevent measles by large doses but rather to cause what might be a fatal attack to be an attenuated one with no complications. The active immunity thus produced will be invaluable, whereas the passive immunity lasts only from two to six weeks in the complete state.

Jejunostomy in Treatment of Massive Gastric Ulcer.—Hillman describes two cases of "massive" gastric ulcer. In each instance the performance of a jejunostomy allowed the general and local conditions to improve so that radical operation became possible. The jejunostomy quickly removed all pain of which the patients complained, showing that rest to the stomach gives relief in these cases. One case illustrates that true rest to the stomach will cause complete healing of a large ulcer in eight months, without the use of alkalis. The case also shows that a patient can be adequately nourished for eight months by means of a jejunostomy and at the same time be rendered fit for an extensive operation. Jejunostomy in no way hinders the performance of a partial gastrectomy. The other case illustrates the spontaneous separation of a gastrojejunostomy. The author concludes that he will not hesitate in repeating the procedure, should occasion arise.

*Antitoxin in Treatment of Scarlatina with Especial Reference to Prevention of Complications. A. H. Imrie—p 36

Antitoxin in Treatment of Scarlatina.—Imrie carried out an investigation to determine the value of antiscarlatinal toxin in the treatment of scarlet fever, with special reference to the prevention of complications and the relative merits of the intramuscular and intravenous routes of administration. He observed that 1. Antitoxin has a beneficial effect on the

initial toxæmia. It slightly reduces the duration of the rash and pyrexia and often induces a fine localized desquamation. Antitoxin in the dosage given (20 cc. to two patients and 30 cc. to one) has no effect on well established toxic scarlet fever. It is of value in preventing complications if given early, i. e., before the fourth day of illness, and preferably on the first or second day. The route of administration has little influence on the initial toxæmia, duration of rash or duration of pyrexia, and little influence on the duration of desquamation in cases that desquamate generally. Antitoxin given intravenously, however induces, in a large proportion of cases, a fine type of desquamation, frequently localized, and for these cases the period of desquamation is markedly reduced. Antitoxin given intravenously appears to reduce the incidence of complications more than that given intramuscularly. Intravenous administration is often difficult in young children may be dangerous, and is contraindicated in the case of any one who has previously had serum or who appears likely to be sensitive to it. In the author's series of 1616 cases of which 294 were treated with antitoxin, there were only 6 cases of endocarditis. These all occurred in the untreated group, and all gave a history of rheumatism.

"Black Spores" of Ross in Mosquitoes—Knowles and Basu believe that the confusion which at present exists in the literature with regard to the "black spores of Ross" is due to the fact that different observers have been dealing with three different structures under that name, viz (1) degenerated and hyperpigmented malarial oocysts, which may be either intact with the investing thin oocyst membrane unruptured, or with the scattered contents of oocysts after their rupture (such structures may possibly act as foreign bodies in the tissues of the mosquito and subsequently become chitinized, the authors consider these, alone, to be the true black spores of Ross) (2) 'chitin corpuscles' which consist of hyperchitinization of localized portions of the finer ramifications of the tracheal system (a study of these forms alone led Mayne to the conclusion that the 'black spores' are of

purely tracheal origin and have nothing to do with the malaria parasites), and (3) fungus infections of the tracheal system of the mosquito possibly in places associated with hyperchitinization. The authors' observations based on material studied in sections led them to the belief that chitin corpuscles and fungal infections of the tracheal system of the mosquito have nothing to do with the true black spores. They give an account of the occurrence of black spores in infected *Anopheles stephensi* after feeding on patients showing infections with *Plasmodium malariae* and *P. falciparum*. The process of evolution of these degenerating and hyperpigmented cysts is described and illustrated. They suggest that the term "black spores," although of historical interest may be rather confusing and perhaps "degenerated and hyperpigmented oocysts" or ruptured contents of oocysts should be substituted.

Cholesterol Content of Blood in Indians—Ghose made an investigation of the cholesterol content of the blood in healthy Indians. The normal average value of blood cholesterol is 146 mg per hundred cubic centimeters of the whole blood and 140 mg per hundred cubic centimeters of the blood plasma yielded by Bloor's method, which is about 40 mg per hundred cubic centimeters less than the European and American standards. A wide range of normal values has also been found in Indians. In vegetarians and mixed dietarians the cholesterol content of the blood is practically the same. A rich fatty diet after fasting gives rise to a temporary increase in the blood cholesterol. The seasonal variations seem to have little effect on the cholesterol content of the blood. The changes in the cholesterol content of the blood plasma which occur in biliary and hepatic diseases show that (1) a low blood cholesterol with slight jaundice is indicative of either cirrhotic or carcinomatous changes in the liver (2) a frankly low plasma cholesterol with a high icterus index is indicative of a malignant growth of the pancreas, gallbladder and adjoining organs, causing obstruction to the flow of bile, and (3) a high blood cholesterol with jaundice is indicative of gallstones causing obstruction; it may or may not be associated with a cancerous condition of the gallbladder and the pancreas.

Blood Cholesterol in Genito-Urinary System—Ghose estimated the cholesterol content of the blood in sixty-two patients suffering from surgical diseases of the genito-urinary system. The results obtained do not point to any significant utility of the determination of the blood cholesterol as a routine method, which would forecast the prognosis in a case of urinary disease. A low blood cholesterol has no prognostic significance in cases of urinary obstruction in which operation has been performed, and there is no justification for refusing to operate on a person suffering from urinary obstruction merely because previous to the proposed operation a low blood cholesterol has been reported. Blood urea below 50 mg per hundred cubic centimeters assures a fair margin of safety, and no direct or indirect relation of the blood urea to the cholesterol content of the blood has been found.

Horseshoe Kidney—Jacobs reports five cases of horseshoe kidney and states that, in the presence of renal disease requiring operative intervention, the preoperative knowledge of the existence of a horseshoe anomaly is a tremendous advantage, particularly in the approach. To those experienced in the interpretation of pyelograms, diagnosis should in most cases be easy.

The only other condition that might give rise to confusion is an anomaly of rotation. When this occurs in an excessive degree, the convex border is mesial and the pelvis faces the side. The pyelogram of such a kidney would show the calices directed toward the spinal column. As both kidneys are not usually rotated, the pyelogram of the other kidney would be likely to have a normal appearance. The important diagnostic features of the pyelogram of a horseshoe kidney are: 1 The shadow lies closer to the midline than in the normal, and is usually lower. 2 The pelvis and calices are of a bizarre shape. 3 One or more of the calices on each side point toward the midline or downward, and some of the calices may overlap the shadow of the pelvis. 4 The upper end of the ureter curves outward from and then inward to the vertebral column. Pyelography is the only reliable diagnostic method. A plain radioscopsy might be suggestive by indicating a loss of outline of the psoas shadow and a failure to visualize the one or the other of the renal poles. There is no syndrome of symptoms and signs characteristic of horseshoe kidney. Diseases involving a horseshoe kidney should be treated in the same manner as similar diseases in kidneys normally formed. If resection of the affected segment is necessary, this involves cutting through the isthmus which is usually composed of parenchymatous tissue. It is the author's custom to make an incision starting about 1 inch below the costovertebral angle. This is carried downward and slightly forward to a point about midway in the costo-iliac space when it is made to pass forward parallel with the iliac crest. The muscles and fascia are divided in the line of the incision, which can be prolonged as far toward the midline as seems necessary to give a free exposure of the isthmus. The complete muscular relaxation obtained by spinal anesthesia greatly facilitates the access

*Erythrocyte Sedimentation Test Clinical and Experimental Study A C R. Walton—p 79

Linitis Plastica—After a careful study of the many reported cases of linitis plastica, and from his personal experience, Howard concludes that the majority of cases belong to the sclerosing type of carcinoma. While he is not in a position to deny the existence of a benign form (the so called fibromatosis), he believes that many of the reported cases have not been submitted to a careful enough histologic scrutiny to exclude a malignant process. While syphilis may be an exciting factor in a certain number of cases he suggests that in the majority of the so called syphilitic leather-bottle stomachs there has been a secondary invasion by cancer cells. The clinical picture of every case, whatever its etiology may be, is that of a rather chronic form of cancer of the stomach. An early exploratory laparotomy should be carried out and, when possible, some radical form of surgical procedure undertaken. Rest, fresh air, a mild and bland nutritious diet, nutrient enemas, gastric lavage, paracentesis of the pleura and peritoneum, opiates and cardiac stimulants prolong life and render the patient's final weeks more comfortable.

Erythrocyte Sedimentation Test.—Walton describes a new and simple technic for the performance of the sedimentation test which avoids certain fallacies and places the test on a standard basis, so that an exact comparison of the sedimentation rate in various samples of blood may be made. He also gives Blacklock's method for bringing the citrated blood, before measurement of the sedimentation rate, to a standard content of 5,000,000 red cells per cubic millimeter. The chief correction is that for an abnormal blood count. The sedimentation rate undergoes appreciable modifications in physiologic states, such as at birth, during pregnancy and menstruation and the higher sedimentation rate in women than in men, and these modifications should be fully appreciated before an attempt is made to evaluate the influence of pathologic conditions on the sedimentation rate. The sedimentation test is a most delicate and sensitive reaction which faithfully reflects the state of equilibrium of the blood in relation to any pathologic process. It is not specific for any disease, and therefore its uses as a specific diagnostic agent are almost limited to the domain of tuberculosis, where it may be employed in conjunction with a small provocative dose of tuberculin. Used cautiously, however, and as an adjunct to the clinical picture, the sedimentation test, if correctly interpreted, will be found to possess great value and will often weigh down the scales of differential diagnosis. In conditions in which there is a suggestion of latent and acute inflammatory processes, accompanied by a normal temperature and leukocyte count, or in obscure carcinomas, the sedimentation test may be utilized to great advantage, just as, on the contrary, the finding of a normal sedimentation rate excludes an active inflammatory or neoplastic process. Probably the most important use for the test is that of a prognostic agent. Clinical improvement is shown by a slowing sedimentation rate, whereas a fatal evolution is invariably accompanied by an increasing rapidity of sedimentation. In any disease, therefore, the response to treatment can be observed, and a vigilance may be maintained on convalescence. The author states that the sedimentation test may be utilized to differentiate between functional and organic lesions, between innocent and malignant conditions—especially of the gastro-intestinal tract—and between inflammatory and noninflammatory lesions. In pediatrics the test may be employed to advantage, since the finding of a rapid sedimentation rate in the new-born or in the apyretic infant who may merely show a lack of normal development will speak for hereditary syphilis, even in the face of a negative Wassermann reaction.

Asthmatic Bronchitis Without Asthma—Under this caption de Gennes discusses the forms of bronchitis in which there is no apparent spasticity but which are nevertheless equivalent to asthma and should be treated as such. He has seen many cases of this kind. Sometimes the diagnosis is guided in the right direction by an anamnesis of real asthma or a related condition, sometimes the appearance, during the course of the bronchitis of a spasmodic or paroxysmal cough terminating in a slight attack of dyspnea, or the long drawn out apyretic character of the disease and its resistance to the usual treatments of bronchitis may indicate its asthmatic origin. Sometimes, but not always, an eosinophilia of the sputum, or occasionally of the blood, will determine the diagnosis of asthma. In some cases there are no clinical or biologic signs to guide the diagnosis and only the response to treatment of asthma establishes the nature of the disease. There are cases still more difficult to diagnose in which the asthmatic bronchitis succeeds an infectious bronchitis and the asthmatic element is not recognized. Spraying the nose with atropine has been recommended for the treatment of these forms of bronchitis. Injections of epinephrine with or without hypophyseal extract sometimes cure them instantly. Ephedrine either sprayed or ingested is a simple and, sometimes, the best treatment. Sunlight and altitude may also produce a rapid cure. Protein therapy has given little success. Three case reports are given.
